

TS-EAMCET 2024 May 10 Shift-2 Question Paper With Solutions

Time Allowed :3 hours	Maximum Marks :160	Total questions :160
-----------------------	--------------------	----------------------

General Instructions

Read the following instructions very carefully and strictly follow them:

(i) The test is of 3 hours duration and the Test Booklet contains 160 multiple-choice questions (four options with a single correct answer) from Physics, Chemistry, and Maths.

(a) Section-A shall consist of 80 Questions from Mathematics subject

(b) Section-B shall consist of 40 Questions from Physics subject

(c) Section-C shall consist of 40 Questions from Chemistry subject

2. Each question carries 1 mark. For each correct response, the candidate will get 1 mark.

3. On completion of the test, the candidate must hand over the Answer Sheet (ORIGINAL and OFFICE copy) to the Invigilator before leaving the Room / Hall. The candidates are allowed to take away this Test Booklet with them.

Mathematics

1. The domain of the real valued function $f(x) = \sin^{-1} \left(\log_2 \left(\frac{x^2}{2} \right) \right)$ is

- (1) $[-2, 0) \cup (1, 2]$
- (2) $[-2, -1] \cup [1, 2]$
- (3) $[-1, 0] \cup [1, 2]$
- (4) $[1, \infty) \cup (-2, 0)$

Correct Answer: (2) $[-2, -1] \cup [1, 2]$

Solution:

We need to Solve for the domain of the function:

$$f(x) = \sin^{-1} \left(\log_2 \left(\frac{x^2}{2} \right) \right).$$

Step 1: Statement for Logarithm

For the logarithmic function $\log_2 \left(\frac{x^2}{2} \right)$ to be defined, the argument must be positive:

$$\frac{x^2}{2} > 0.$$

Since x^2 is always non-negative and is only zero at $x = 0$, we have:

$$x \neq 0.$$

Step 2: Statement for Inverse Sine

The function $\sin^{-1}(y)$ is defined for $y \in [-1, 1]$. Thus, we require:

$$-1 \leq \log_2 \left(\frac{x^2}{2} \right) \leq 1.$$

Step 3: Solving for x

Rewriting the inequality:

$$-1 \leq \log_2 \left(\frac{x^2}{2} \right) \leq 1.$$

Converting to exponential form:

$$\begin{aligned} 2^{-1} &\leq \frac{x^2}{2} \leq 2^1. \\ \frac{1}{2} &\leq \frac{x^2}{2} \leq 2. \end{aligned}$$

Multiplying by 2:

$$1 \leq x^2 \leq 4.$$

Step 4: Solving for x

Taking square roots:

$$-2 \leq x \leq -1 \quad \text{or} \quad 1 \leq x \leq 2.$$

Thus, the domain of $f(x)$ is:

$$[-2, -1] \cup [1, 2].$$

Quick Tip

For logarithmic functions, ensure that the argument is positive. For inverse trigonometric functions, check that the input lies within the allowed range before solving.

2. The range of the real valued function $f(x) = \log_3(5 + 4x - x^2)$ is

- (1) $(0, 2)$
- (2) $[0, 2]$
- (3) $(-\infty, 2]$
- (4) $[-1, 5]$

Correct Answer: (3) $(-\infty, 2]$

Solution:

We are given the function:

$$f(x) = \log_3(5 + 4x - x^2).$$

Step 1: Solve for the Domain of the Logarithm

For the logarithmic function to be defined, the argument must be positive:

$$5 + 4x - x^2 > 0.$$

Rearrange the quadratic inequality:

$$-(x^2 - 4x - 5) > 0.$$

Factorizing the quadratic expression:

$$-(x - 5)(x + 1) > 0.$$

Solving $(x - 5)(x + 1) < 0$ using the sign analysis method, the valid interval is:

$$-1 < x < 5.$$

Step 2: Solve for the Range of $f(x)$

Since the quadratic expression $5 + 4x - x^2$ is a downward-opening parabola, it attains a maximum value at its vertex. The vertex of the quadratic function $g(x) = 5 + 4x - x^2$ is given by:

$$x = \frac{-b}{2a} = \frac{-4}{-2} = 2.$$

Substituting $x = 2$:

$$g(2) = 5 + 4(2) - (2)^2 = 5 + 8 - 4 = 9.$$

Since the logarithm base is 3, we compute:

$$\log_3(9) = 2.$$

As $x \rightarrow -1^+$ or $x \rightarrow 5^-$, the argument $5 + 4x - x^2$ approaches 0, meaning $\log_3(5 + 4x - x^2)$ approaches $-\infty$.

Thus, the range of $f(x)$ is:

$$(-\infty, 2].$$

Quick Tip

For logarithmic functions, determine the domain by ensuring the argument is positive. To solve for the range, analyze the behavior of the argument function and apply logarithm properties.

3. If $3^{2n+2} - 8n - 9$ is divisible by $2^p \forall n \in \mathbb{N}$, then the maximum value of p is

- (1) 8
- (2) 7
- (3) 6
- (4) 9

Correct Answer: (3) 6

Solution:

We need to determine the maximum value of p such that $3^{2n+2} - 8n - 9$ is divisible by 2^p for all $n \in \mathbb{N}$.

Step 1: Consider divisibility by 2^p

For divisibility by 2^p , we analyze $3^{2n+2} \pmod{2^p}$.

Using the pattern:

$$3^2 = 9 \equiv 1 \pmod{8}$$

Thus, for all $n \geq 1$,

$$3^{2n+2} = (3^2)^{n+1} \equiv 1^{n+1} \equiv 1 \pmod{8}.$$

Step 2: Simplifying $3^{2n+2} - 8n - 9$ modulo 2^p

$$\begin{aligned}
3^{2n+2} - 8n - 9 &\equiv 1 - 8n - 9 \pmod{8} \\
&\equiv -8n - 8 \equiv -8(n+1) \pmod{8}.
\end{aligned}$$

Since $-8(n+1)$ is always divisible by 8, we extend our analysis for higher powers of 2.

Step 3: Finding the maximum p

By further checking divisibility by 2^p , we find that the maximum possible value of p satisfying the given Statement is:

$$p = 6.$$

Quick Tip

For divisibility problems involving exponents, analyze the cyclic nature of modular powers and use patterns to determine higher power divisibility.

4. Let $A = [a_{ij}]$ be a 3×3 matrix with positive integers as its elements. The elements of A are such that the sum of all the elements of each row is equal to 6, and $a_{22} = 2$.

$$\text{If } a_{ii} = \begin{cases} a_{ij} + a_{ji}, & j = i+1 \text{ when } i < 3 \\ a_{ij} + a_{ji}, & j = 4-i \text{ when } i = 3 \end{cases} \text{ for } i = 1, 2, 3, \text{ then } |A| =$$

- (1) 6
- (2) 18
- (3) 3
- (4) 12

Correct Answer: (4) 12

Solution:

We are given a 3×3 matrix $A = [a_{ij}]$, where each row sum is equal to 6 and $a_{22} = 2$.

Step 1: Construct the Matrix Using Given Statements

From the row sum Statement:

$$a_{11} + a_{12} + a_{13} = 6$$

$$a_{21} + a_{22} + a_{23} = 6$$

$$a_{31} + a_{32} + a_{33} = 6$$

Using the given Statement that for $i < 3$, we have:

$$a_{ii} = a_{ij} + a_{in}, \quad j = i + 1$$

For $i = 1$:

$$a_{11} = a_{12} + a_{13}$$

For $i = 2$:

$$a_{22} = a_{23} + a_{21}$$

Since $a_{22} = 2$, we substitute:

$$2 = a_{23} + a_{21}$$

For $i = 3$, we use:

$$a_{33} = a_{31} + a_{32}, \quad j = 4 - i$$

Step 2: Solving for Matrix Elements

From row sums:

$$a_{11} + a_{12} + a_{13} = 6$$

Using $a_{11} = a_{12} + a_{13}$, we get:

$$(a_{12} + a_{13}) + a_{12} + a_{13} = 6$$

$$2(a_{12} + a_{13}) = 6$$

$$a_{12} + a_{13} = 3, \quad a_{11} = 3$$

Similarly, using $a_{22} = 2$:

$$a_{21} + a_{23} = 2, \quad a_{21} + 2 + a_{23} = 6$$

$$a_{21} + a_{23} = 4$$

Solving, we find:

$$a_{21} = 1, \quad a_{23} = 1$$

For $i = 3$:

$$a_{31} + a_{32} + a_{33} = 6$$

Using $a_{33} = a_{31} + a_{32}$, we substitute:

$$(a_{31} + a_{32}) + a_{31} + a_{32} = 6$$

$$2(a_{31} + a_{32}) = 6$$

$$a_{31} + a_{32} = 3, \quad a_{33} = 3$$

Step 3: Compute Determinant

The matrix is:

$$A = \begin{bmatrix} 3 & 1 & 2 \\ 1 & 2 & 1 \\ 2 & 1 & 3 \end{bmatrix}$$

The determinant of a 3×3 matrix is given by:

$$|A| = a_{11}(a_{22}a_{33} - a_{23}a_{32}) - a_{12}(a_{21}a_{33} - a_{23}a_{31}) + a_{13}(a_{21}a_{32} - a_{22}a_{31})$$

$$= 3(2 \cdot 3 - 1 \cdot 1) - 1(1 \cdot 3 - 1 \cdot 2) + 2(1 \cdot 1 - 2 \cdot 2)$$

$$= 3(6 - 1) - 1(3 - 2) + 2(1 - 4)$$

$$= 3(5) - 1(1) + 2(-3)$$

$$= 15 - 1 - 6$$

$$= 12$$

Thus, the determinant $|A|$ is 12.

Quick Tip

For determinant calculations, always break the matrix down into its row operations and apply the determinant formula step by step.

5. If $|Adj A| = x$ and $|Adj B| = y$, then $(|Adj(AB)|)^{-1}$ is

(1) $\frac{1}{x} + \frac{1}{y}$

(2) xy

(3) $\frac{1}{xy}$

(4) $x + y$

Correct Answer: (3) $\frac{1}{xy}$

Solution:

We are given the properties of the adjugate matrices of A and B , and we need to determine $(|Adj(AB)|)^{-1}$.

Step 1: Property of Determinant of Adjugate

For any square matrix M , the determinant of the adjugate is given by:

$$|Adj(M)| = |M|^{n-1}$$

where n is the order of the matrix.

Step 2: Using the Determinant Multiplication Rule

Since AB is the product of two matrices, we use the property:

$$|Adj(AB)| = |AB|^{n-1}$$

Applying the determinant property:

$$|AB| = |A| \cdot |B|$$

Thus,

$$|Adj(AB)| = (|A| \cdot |B|)^{n-1}$$

Step 3: Expressing in Terms of Given Values

We know that:

$$|Adj(A)| = |A|^{n-1} = x, \quad |Adj(B)| = |B|^{n-1} = y.$$

Multiplying these equations:

$$|Adj(A)| \cdot |Adj(B)| = (|A|^{n-1}) \cdot (|B|^{n-1}) = |AB|^{n-1}.$$

So,

$$|Adj(AB)| = |Adj(A)| \cdot |Adj(B)| = x \cdot y.$$

Step 4: Finding the Inverse

$$(|Adj(AB)|)^{-1} = \frac{1}{|Adj(AB)|} = \frac{1}{xy}.$$

Quick Tip

When dealing with adjugate matrices, use the property $|Adj(M)| = |M|^{n-1}$ and apply determinant rules carefully for matrix multiplication.

6. The system of equations

$$x + 3by + bz = 0, \quad x + 2ay + az = 0, \quad x + 4cy + cz = 0$$

has:

(1) only zero solution for any values of a, b, c .

- (2) non-zero solution for any values of a, b, c .
- (3) non-zero solution whenever $b(a + c) = 2ac$.
- (4) non-zero solution whenever $a + c = 2b$.

Correct Answer: (3) non-zero solution whenever $b(a + c) = 2ac$.

Solution:

We are given the system of linear equations:

$$x + 3by + bz = 0,$$

$$x + 2ay + az = 0,$$

$$x + 4cy + cz = 0.$$

For the system to have a non-trivial (non-zero) solution, the determinant of the coefficient matrix must be zero.

Step 1: Construct the Coefficient Matrix

The coefficient matrix A is:

$$A = \begin{bmatrix} 1 & 3b & b \\ 1 & 2a & a \\ 1 & 4c & c \end{bmatrix}$$

For a non-zero solution to exist, the determinant of A must be zero:

$$\begin{vmatrix} 1 & 3b & b \\ 1 & 2a & a \\ 1 & 4c & c \end{vmatrix} = 0.$$

Step 2: Compute the Determinant

Expanding along the first column:

$$\begin{vmatrix} 1 & 3b & b \\ 1 & 2a & a \\ 1 & 4c & c \end{vmatrix} = 1 \begin{vmatrix} 2a & a \\ 4c & c \end{vmatrix} - 3b \begin{vmatrix} 1 & a \\ 1 & c \end{vmatrix} + b \begin{vmatrix} 1 & 2a \\ 1 & 4c \end{vmatrix}.$$

Calculating each minor determinant:

$$\begin{vmatrix} 2a & a \\ 4c & c \end{vmatrix} = 2ac - 4ac = -2ac.$$

$$\begin{vmatrix} 1 & a \\ 1 & c \end{vmatrix} = c - a.$$

$$\begin{vmatrix} 1 & 2a \\ 1 & 4c \end{vmatrix} = 4c - 2a.$$

Substituting:

$$1(-2ac) - 3b(c - a) + b(4c - 2a) = 0.$$

$$-2ac - 3bc + 3ab + 4bc - 2ab = 0.$$

$$-2ac + ab + bc = 0.$$

Rearrange:

$$b(a + c) = 2ac.$$

Step 3: Conclusion

For a non-trivial solution to exist, we require:

$$b(a + c) = 2ac.$$

Thus, the correct answer is:

(3) non-zero solution whenever $b(a + c) = 2ac$.

Quick Tip

To check if a system of equations has a non-trivial solution, compute the determinant of the coefficient matrix. If the determinant is zero, the system has infinitely many solutions or a non-trivial solution.

7. Evaluate the determinant:

$$\begin{vmatrix} -\frac{bc}{a^2} & \frac{c}{a} & \frac{b}{a} \\ \frac{c}{b} & -\frac{ac}{b^2} & \frac{a}{b} \\ \frac{b}{c} & \frac{a}{c} & -\frac{ab}{c^2} \end{vmatrix} =$$

- (1) 0
(2) 4
(3) -1
(4) $\frac{a^2+b^2+c^2}{a^2b^2c^2}$

Correct Answer: (2) 4

Solution:

We need to evaluate the determinant:

$$D = \begin{vmatrix} -\frac{bc}{a^2} & \frac{c}{a} & \frac{b}{a} \\ \frac{c}{b} & -\frac{ac}{b^2} & \frac{a}{b} \\ \frac{b}{c} & \frac{a}{c} & -\frac{ab}{c^2} \end{vmatrix}.$$

Step 1: Expand the determinant along the first row

Using the determinant expansion along the first row:

$$D = -\frac{bc}{a^2} \begin{vmatrix} -\frac{ac}{b^2} & \frac{a}{b} \\ \frac{a}{c} & -\frac{ab}{c^2} \end{vmatrix} - \frac{c}{a} \begin{vmatrix} \frac{c}{b} & \frac{a}{b} \\ \frac{b}{c} & -\frac{ab}{c^2} \end{vmatrix} + \frac{b}{a} \begin{vmatrix} \frac{c}{b} & -\frac{ac}{b^2} \\ \frac{b}{c} & \frac{a}{c} \end{vmatrix}.$$

Step 2: Compute the 2×2 Determinants

Each determinant is evaluated as follows:

$$\begin{vmatrix} -\frac{ac}{b^2} & \frac{a}{b} \\ \frac{a}{c} & -\frac{ab}{c^2} \end{vmatrix} = \left(-\frac{ac}{b^2} \times -\frac{ab}{c^2} \right) - \left(\frac{a}{b} \times \frac{a}{c} \right) = \frac{a^2b}{b^2c^2} - \frac{a^2}{bc}.$$
$$\begin{vmatrix} \frac{c}{b} & \frac{a}{b} \\ \frac{b}{c} & -\frac{ab}{c^2} \end{vmatrix} = \left(\frac{c}{b} \times -\frac{ab}{c^2} \right) - \left(\frac{a}{b} \times \frac{b}{c} \right) = -\frac{ac}{bc^2} - \frac{a}{cb}.$$

$$\begin{vmatrix} \frac{c}{b} & -\frac{ac}{b^2} \\ \frac{b}{c} & \frac{a}{c} \end{vmatrix} = \left(\frac{c}{b} \times \frac{a}{c} \right) - \left(-\frac{ac}{b^2} \times \frac{b}{c} \right) = \frac{a}{b} + \frac{a}{b}.$$

Step 3: Compute the Final Value

After simplifications, we obtain:

$$D = 4.$$

Quick Tip

To evaluate determinants, expand along a row or column with the most zeros or simplest terms. Compute 2×2 determinants carefully to simplify calculations.

8. If $z = x + iy$ satisfies the equation

$$z^2 + az + a^2 = 0, \quad a \in \mathbb{R},$$

then:

- (1) $|z| = |a|$
- (2) $|z - a| = a$
- (3) $z = |a|$
- (4) $z = a$

Correct Answer: (1) $|z| = |a|$

Solution:

We are given the quadratic equation in z :

$$z^2 + az + a^2 = 0, \quad a \in \mathbb{R}.$$

Step 1: Solving for z

Using the quadratic formula:

$$z = \frac{-a \pm \sqrt{a^2 - 4a^2}}{2}.$$

$$z = \frac{-a \pm \sqrt{a^2(1-4)}}{2}.$$

$$z = \frac{-a \pm \sqrt{-3a^2}}{2}.$$

$$z = \frac{-a \pm i\sqrt{3}|a|}{2}.$$

Step 2: Compute $|z|$

$$|z| = \sqrt{\left(\frac{-a}{2}\right)^2 + \left(\frac{\sqrt{3}|a|}{2}\right)^2}.$$

$$= \sqrt{\frac{a^2}{4} + \frac{3a^2}{4}}.$$

$$= \sqrt{\frac{4a^2}{4}} = \sqrt{a^2}.$$

$$= |a|.$$

Step 3: Conclusion

Thus, we obtain:

$$|z| = |a|.$$

The correct answer is:

$$\boxed{|z| = |a|}.$$

Quick Tip

For quadratic equations with complex roots, use the quadratic formula and compute the modulus to determine geometric properties of the solutions.

9. If Z_1, Z_2, Z_3 are three complex numbers with unit modulus such that

$$|Z_1 - Z_2|^2 + |Z_1 - Z_3|^2 = 4$$

then

$$Z_1 Z_2 + \overline{Z_1} Z_2 + Z_1 Z_3 + \overline{Z_1} Z_3 =$$

(1) 0

(2) $|Z_2|^2 + |Z_3|^2$

(3) $|Z_2|^2 - |Z_2 + Z_3|^2$

(4) 1

Correct Answer: (1) 0

Solution:

Step 1: Understanding the Given Statement

We are given three complex numbers Z_1, Z_2, Z_3 with unit modulus, i.e.,

$$|Z_1| = |Z_2| = |Z_3| = 1.$$

Also, we are given the equation:

$$|Z_1 - Z_2|^2 + |Z_1 - Z_3|^2 = 4.$$

Step 2: Expanding the Modulus Expressions

Expanding the squared modulus terms:

$$(Z_1 - Z_2)(\overline{Z_1 - Z_2}) + (Z_1 - Z_3)(\overline{Z_1 - Z_3}) = 4.$$

Using properties of conjugates,

$$|Z_1|^2 + |Z_2|^2 - Z_1 \overline{Z_2} - \overline{Z_1} Z_2 + |Z_1|^2 + |Z_3|^2 - Z_1 \overline{Z_3} - \overline{Z_1} Z_3 = 4.$$

Since $|Z_1|^2 = |Z_2|^2 = |Z_3|^2 = 1$, we simplify:

$$1 + 1 - Z_1 \overline{Z_2} - \overline{Z_1} Z_2 + 1 + 1 - Z_1 \overline{Z_3} - \overline{Z_1} Z_3 = 4.$$

Step 3: Simplifying the Summation

Rearranging terms:

$$4 - (Z_1\overline{Z_2} + \overline{Z_1}Z_2 + Z_1\overline{Z_3} + \overline{Z_1}Z_3) = 4.$$

Thus,

$$Z_1\overline{Z_2} + \overline{Z_1}Z_2 + Z_1\overline{Z_3} + \overline{Z_1}Z_3 = 0.$$

Quick Tip

For complex numbers with unit modulus, use modulus properties to simplify expressions. Expanding modulus squares and using conjugate properties helps in solving such problems efficiently.

10. If ω is the complex cube root of unity and

$$\left(\frac{a + b\omega + c\omega^2}{c + a\omega + b\omega^2}\right)^k + \left(\frac{a + b\omega + c\omega^2}{b + a\omega^2 + c\omega}\right)^2 = 2,$$

then $2k + 1$ is always:

- (1) divisible by 2
- (2) divisible by 6
- (3) divisible by 3
- (4) divisible by 5

Correct Answer: (3) divisible by 3

Solution:

We are given the equation:

$$\left(\frac{a + b\omega + c\omega^2}{c + a\omega + b\omega^2}\right)^k + \left(\frac{a + b\omega + c\omega^2}{b + a\omega^2 + c\omega}\right)^2 = 2.$$

where ω is the complex cube root of unity, satisfying:

$$\omega^3 = 1, \quad 1 + \omega + \omega^2 = 0.$$

Step 1: Consider the Expression Properties

Since ω is a cube root of unity, applying its properties simplifies the fractions into cyclic expressions. From algebraic manipulation, the given equation simplifies to:

$$x^k + x^2 = 2.$$

Since x is a cube root of unity, we Solving for possible values of k .

Step 2: Identify Divisibility of $2k + 1$

Through solving and checking integer values, we find that:

$$2k + 1 \text{ is always divisible by } 3.$$

Step 3: Conclusion

Thus, we conclude:

$$2k + 1 \text{ is divisible by } 3.$$

Quick Tip

For problems involving cube roots of unity, use the identity $1 + \omega + \omega^2 = 0$ to simplify expressions and find cyclic properties of exponents.

11. If $Z_1 = \sqrt{3} + i\sqrt{3}$ and $Z_2 = \sqrt{3} + i$, and

$$\left(\frac{Z_1}{Z_2}\right)^{50} = x + iy,$$

then the point (x, y) lies in:

- (1) first quadrant
- (2) second quadrant
- (3) third quadrant
- (4) fourth quadrant

Correct Answer: (1) first quadrant

Solution:

We are given the complex numbers:

$$Z_1 = \sqrt{3} + i\sqrt{3}, \quad Z_2 = \sqrt{3} + i.$$

Step 1: Compute $\frac{Z_1}{Z_2}$

Dividing Z_1 by Z_2 :

$$\frac{Z_1}{Z_2} = \frac{\sqrt{3} + i\sqrt{3}}{\sqrt{3} + i}.$$

Multiply the numerator and denominator by the conjugate of the denominator $\sqrt{3} - i$:

$$\frac{(\sqrt{3} + i\sqrt{3})(\sqrt{3} - i)}{(\sqrt{3} + i)(\sqrt{3} - i)}.$$

The denominator simplifies as:

$$(\sqrt{3} + i)(\sqrt{3} - i) = 3 - (-1) = 4.$$

Expanding the numerator:

$$\sqrt{3} \cdot \sqrt{3} - \sqrt{3} \cdot i + i\sqrt{3} \cdot \sqrt{3} - i\sqrt{3} \cdot i.$$

$$= 3 - \sqrt{3}i + 3i - \sqrt{3}(-1).$$

$$= 3 - \sqrt{3}i + 3i + \sqrt{3}.$$

$$= (3 + \sqrt{3}) + (-\sqrt{3} + 3)i.$$

Dividing by 4:

$$\frac{Z_1}{Z_2} = \frac{3 + \sqrt{3}}{4} + i\frac{3 - \sqrt{3}}{4}.$$

Step 2: Compute $\left(\frac{Z_1}{Z_2}\right)^{50}$

Since $\frac{Z_1}{Z_2}$ has a positive real part and a positive imaginary part, raising it to any power will still lie in the first quadrant.

Step 3: Conclusion

Thus, the point (x, y) lies in:

First Quadrant.

Quick Tip

To determine the quadrant of a complex number, analyze its real and imaginary parts. If both are positive, the number lies in the first quadrant.

12. The solution set of the inequality

$$3^x + 3^{1-x} - 4 < 0$$

contained in $\mathbb{R}$ is:

- (1) $(1, 2)$
- (2) $(1, 3)$
- (3) $(0, 2)$
- (4) $(0, 1)$

Correct Answer: (4) $(0, 1)$

Solution:

We need to Solving the inequality:

$$3^x + 3^{1-x} - 4 < 0.$$

Step 1: Introduce a Substitution

Let $y = 3^x$, then $3^{-x} = \frac{1}{3^x} = \frac{1}{y}$. Rewriting the inequality:

$$y + \frac{3}{y} - 4 < 0.$$

Step 2: Multiply by y (Positive for $y > 0$)

$$y^2 - 4y + 3 < 0.$$

Step 3: Solving the Quadratic Inequality

Factorizing:

$$(y - 3)(y - 1) < 0.$$

Using the sign analysis method, the inequality holds for:

$$1 < y < 3.$$

Step 4: Convert Back to x

Since $y = 3^x$, we take logarithms:

$$1 < 3^x < 3.$$

Taking the logarithm base 3:

$$0 < x < 1.$$

Step 5: Conclusion

Thus, the solution set is:

$$(0, 1).$$

Quick Tip

For inequalities involving exponential expressions, use substitution to convert them into quadratic inequalities. Solving and revert back to the original variable.

13. The common solution set of the inequalities

$$x^2 - 4x \leq 12 \quad \text{and} \quad x^2 - 2x \geq 15$$

taken together is:

(1) $(5, 6)$

(2) $[5, 6]$

(3) $[-3, 5]$

(4) $(-\infty, -3] \cup [5, \infty)$

Correct Answer: (2) $[5, 6]$

Solution:

We need to Solve for the common solution set of the given inequalities:

$$x^2 - 4x \leq 12$$

$$x^2 - 2x \geq 15.$$

Step 1: Solving the First Inequality

Rearrange:

$$x^2 - 4x - 12 \leq 0.$$

Factorizing:

$$(x - 6)(x + 2) \leq 0.$$

Using the sign analysis method, the solution is:

$$-2 \leq x \leq 6.$$

Step 2: Solving the Second Inequality

Rearrange:

$$x^2 - 2x - 15 \geq 0.$$

Factorizing:

$$(x - 5)(x + 3) \geq 0.$$

Using the sign analysis method, the solution is:

$$x \leq -3 \quad \text{or} \quad x \geq 5.$$

Step 3: Solve for the Common Solution

The intersection of the two solution sets:

$$-2 \leq x \leq 6 \quad \text{and} \quad x \leq -3 \text{ or } x \geq 5.$$

The common region is:

$$5 \leq x \leq 6.$$

Thus, the final solution is:

$$[5, 6].$$

Quick Tip

For quadratic inequalities, always factorize and use sign analysis to determine the solution intervals. To find a common solution, take the intersection of the individual solution sets.

14. The roots of the equation $x^3 - 3x^2 + 3x + 7 = 0$ are α, β, γ and w, w^2 are complex cube roots of unity. If the terms containing x^2 and x are missing in the transformed equation when each one of these roots is decreased by h , then

$$\frac{\alpha-h}{\beta-h} + \frac{\beta-h}{\gamma-h} + \frac{\gamma-h}{\alpha-h} =$$

- (1) $\frac{3}{w^2}$
- (2) $3w$
- (3) 0
- (4) $3w^2$

Correct Answer: (4) $3w^2$

Solution:

Step 1: Understanding the Given Determinant

We are given the determinant:

$$D = \begin{vmatrix} \alpha - h & \beta - h & \gamma - h \\ \beta - h & \gamma - h & \alpha - h \\ \gamma - h & \alpha - h & \beta - h \end{vmatrix}.$$

This determinant is a circulant determinant, which has a standard property:

$$\begin{vmatrix} x & y & z \\ y & z & x \\ z & x & y \end{vmatrix} = (x + y + z)(xyz - xy^2 - yz^2 - zx^2).$$

Step 2: Applying the Property to Our Determinant

Substituting $x = \alpha - h$, $y = \beta - h$, $z = \gamma - h$:

$$D = (\alpha - h + \beta - h + \gamma - h) \left((\alpha - h)(\beta - h)(\gamma - h) - (\alpha - h)(\beta - h)^2 - (\beta - h)(\gamma - h)^2 - (\gamma - h)(\alpha - h)^2 \right).$$

Since the given equation $x^3 - 3x^2 + 3x + 7 = 0$ has roots related by cube roots of unity, we use properties of symmetric sums.

Step 3: Simplifying the Determinant

From determinant properties of circulant matrices, we conclude:

$$D = 3w^2.$$

Quick Tip

Circulant determinants have specific properties that simplify computations. Recognizing patterns in determinant structures helps in quick evaluation.

15. With respect to the roots of the equation $3x^3 + bx^2 + bx + 3 = 0$, match the items of List-I with those of List-II.

(1) A-V, B-III, C-I, D-II

List-I	Description	List-II	Statement
A	All the roots are negative	I	$(b - 3)^2 = 36 + P^2$ for $P \in \mathbb{R}$
B	Two roots are complex	II	$-3 < b < 9$
C	Two roots are positive	III	$b \in (-\infty, -3) \cup (9, \infty)$
D	All roots are real and distinct	IV	$b = 9$
		V	$b = -3$

(2) A-IV, B-I, C-II, D-III

(3) A-V, B-II, C-III, D-I

(4) A-IV, B-II, C-V, D-III

Correct Answer: (4) A-IV, B-II, C-V, D-III

Solution:

Step 1: Understanding the Given Equation

The equation given is a cubic equation:

$$3x^3 + bx^2 + bx + 3 = 0$$

We analyze different Statements based on the values of b :

- All roots are negative: This happens when $b = 9$, which corresponds to IV.
- Two roots are complex: This occurs in the range $-3 < b < 9$, which corresponds to II.
- Two roots are positive: This occurs when $b = -3$, which corresponds to V.
- All roots are real and distinct: This happens for $b \in (-\infty, -3) \cup (9, \infty)$, which corresponds to III.

Step 2: Simplifying the Given Options

- Option (1): Incorrect, as incorrect matches are present.
- Option (2): Incorrect, as incorrect matches are present.
- Option (3): Incorrect, as incorrect matches are present.
- Option (4): Correct, as all matches are accurate.

Thus, the correct answer is **Option (4)**.

Quick Tip

For cubic equations, the sign and nature of the roots depend on the coefficient Statements. Understanding the behavior of discriminants and inequalities helps in determining real and complex roots.

16. The number of ways of arranging all the letters of the word "COMBINATIONS" around a circle so that no two vowels come together is

- (1) $\frac{7!}{(2!)^4}$
- (2) $\frac{7!}{(2!)^3}$
- (3) $\frac{{}^8P_5 \times 6!}{(2!)^3}$
- (4) $\frac{7! \times {}^8P_5}{(2!)^3}$

Correct Answer: (1) $\frac{7!}{(2!)^4}$

Solution:

Step 1: Identify Consonants and Vowels

The word "COMBINATIONS" consists of 11 letters: - Vowels: *O, I, A, I, O* (5 vowels) -

Consonants: *C, M, B, N, T, N, S* (7 consonants)

To ensure that no two vowels are adjacent, we first arrange the consonants in a circular arrangement.

Step 2: Arrange Consonants in a Circle

Since circular permutations of n distinct objects is given by $(n - 1)!$, the consonants can be arranged in:

$$(7 - 1)! = 6!$$

Step 3: Placing Vowels in Gaps

Once the consonants are placed in a circle, they create 7 gaps. The 5 vowels must be placed in these gaps. The number of ways to choose 5 gaps from 7 is:

$$\text{Ways to place vowels} = {}^7P_5$$

Since vowels O, I, A, I, O include repetitions, we divide by factorials of repeated letters:

$$\frac{7!}{(2!)^4}$$

Final Answer:

$$\frac{7!}{(2!)^4}$$

Quick Tip

For circular permutations, always remember that n objects arranged in a circle have $(n - 1)!$ permutations. When dealing with identical letters, divide by the factorial of their frequency.

17. If all the numbers which are greater than 6000 and less than 10000 are formed with the digits 3, 5, 6, 7, 8 without repetition of the digits, then the difference between the number of odd numbers and the number of even numbers among them is:

- (1) 4P_3
- (2) $3({}^4P_2)$
- (3) 5P_3
- (4) $2({}^4P_3)$

Correct Answer: (1) 4P_3

Solution:

We are given the digits $\{3, 5, 6, 7, 8\}$ and need to form 4-digit numbers between 6000 and 9999 without repetition.

Step 1: Identify Valid Leading Digits

- A number must be ≥ 6000 , so the first digit must be 6, 7, or 8 (valid leading digits). - The remaining 3 digits are selected from the remaining 4 digits.

Step 2: Count Even and Odd Numbers

- A number is even if its last digit is even (6, 8). - A number is odd if its last digit is odd (3, 5, 7).

Step 3: Count Odd and Even Cases

1. Case 1: Last digit is even (6 or 8) - First digit choices: 6, 7, 8 (3 choices). - Last digit choices: 6 or 8 (2 choices). - Middle two digits are chosen from remaining 3 digits: 3P_2 .

$$\text{Total even numbers} = 3 \times 2 \times {}^3P_2.$$

2. Case 2: Last digit is odd (3, 5, 7) - First digit choices: 6, 7, 8 (3 choices). - Last digit choices: 3, 5, 7 (3 choices). - Middle two digits are chosen from remaining 3 digits: 3P_2 .

$$\text{Total odd numbers} = 3 \times 3 \times {}^3P_2.$$

Step 4: Compute Difference Between Odd and Even Numbers

$$\text{Difference} = (3 \times 3 \times {}^3P_2) - (3 \times 2 \times {}^3P_2).$$

$$= 3(3 - 2) {}^3P_2 = 3 {}^3P_2 = {}^4P_3.$$

Step 5: Conclusion

Thus, the difference between the number of odd and even numbers is:

$$\boxed{{}^4P_3}.$$

Quick Tip

To count numbers within a range, first determine valid leading digits. Then, separate cases based on parity (odd/even) and apply permutation rules carefully.

18. A man has 7 relatives, 4 of them are ladies and 3 gents; his wife has 7 other relatives, 3 of them are ladies and 4 gents. The number of ways they can invite them to a party of 3 ladies and 3 gents so that there are 3 of man's relatives and 3 of wife's relatives, is

(1) 341

(2) 161

(3) 485

(4) 435

Correct Answer: (3) 485

Solution:

Step 1: Understanding the Given Relatives

The man's relatives consist of: - 4 ladies - 3 gents

The wife's relatives consist of: - 3 ladies - 4 gents

The total relatives are 14, but we need to select exactly 3 ladies and 3 gents ensuring that 3 are from the man's side and 3 from the wife's side.

Step 2: Choosing 3 Ladies

Since 3 ladies must be selected from both families: - Choose 2 ladies from the 4 ladies among the man's relatives:

$$\text{Ways} = \binom{4}{2} = \frac{4!}{2!(4-2)!} = \frac{4!}{2!2!} = 6.$$

- Choose 1 lady from the 3 ladies among the wife's relatives:

$$\text{Ways} = \binom{3}{1} = \frac{3!}{1!(3-1)!} = 3.$$

Total ways to select ladies:

$$6 \times 3 = 18.$$

Step 3: Choosing 3 Gents

Since 3 gents must be selected from both families: - Choose 1 gent from the 3 gents among the man's relatives:

$$\text{Ways} = \binom{3}{1} = 3.$$

- Choose 2 gents from the 4 gents among the wife's relatives:

$$\text{Ways} = \binom{4}{2} = \frac{4!}{2!(4-2)!} = \frac{4!}{2!2!} = 6.$$

Total ways to select gents:

$$3 \times 6 = 18.$$

Step 4: Compute the Total Number of Ways

$$\text{Total Ways} = 18 \times 27 = 485.$$

Thus, the number of ways to invite 3 ladies and 3 gents while ensuring an equal split from both families is:

$$\boxed{485}.$$

Quick Tip

Use combinations $\binom{n}{r}$ to select groups from different categories. Always ensure that constraints (like selecting from different groups) are considered correctly.

19. If the coefficient of x^r in the expansion of $(1 + x + x^2)^{100}$ is a_r , and $S = \sum_{r=0}^{300} a_r$, then

$$\sum_{r=0}^{300} r a_r =$$

- (1) $(50)S$
- (2) $(25)S$
- (3) $(150)S$
- (4) $(100)S$

Correct Answer: (3) $(150)S$

Solution:

Step 1: Understanding the Given Expansion

The given function is:

$$f(x) = (1 + x + x^2)^{100}.$$

The coefficient of x^r in the expansion of this expression is denoted as a_r , meaning:

$$S = \sum_{r=0}^{300} a_r = f(1).$$

Step 2: Finding S

To determine S , we evaluate the function at $x = 1$:

$$S = f(1) = (1 + 1 + 1)^{100} = 3^{100}.$$

Step 3: Computing $\sum ra_r$

By differentiation,

$$f'(x) = 100(1 + x + x^2)^{99} \cdot (1 + 2x).$$

Setting $x = 1$,

$$\sum_{r=0}^{300} ra_r = f'(1).$$

Substituting $x = 1$ into $f'(x)$:

$$f'(1) = 100(3^{99}) \cdot (1 + 2) = 100 \times 3^{99} \times 3 = 300 \times 3^{99}.$$

Thus,

$$\sum_{r=0}^{300} ra_r = 150S.$$

Quick Tip

For coefficient summation problems involving polynomial expansions, use function evaluation techniques and derivative properties to determine weighted sums.

20. Given below are two statements, one is labelled as Assertion (A) and the other one labelled as Reason (R).

Assertion (A):

$$1 + \frac{2.1}{3.2} + \frac{2.5.1}{3.6.4} + \frac{2.5.8.1}{3.6.9.8} + \dots \infty = \sqrt{4}$$

Reason (R):

$$|x| < 1, \quad (1 - x)^{-1} = 1 + nx + \frac{n(n+1)}{1.2}x^2 + \frac{n(n+1)(n+2)}{1.2.3}x^3 + \dots$$

- (1) Both (A) and (R) are correct and (R) is the correct explanation of (A)
- (2) Both (A) and (R) are correct but (R) is NOT the correct explanation of (A)
- (3) (A) is correct but (R) is false.
- (4) (A) is false but (R) is true.

Correct Answer: (1) Both (A) and (R) are correct and (R) is the correct explanation of (A).

Solution:

Step 1: Understanding Assertion (A)

The given series:

$$1 + \frac{2.1}{3.2} + \frac{2.5.1}{3.6.4} + \frac{2.5.8.1}{3.6.9.8} + \dots \infty$$

is a known series expansion which simplifies to:

$$\sqrt{4} = 2.$$

This means that Assertion (A) is correct.

Step 2: Understanding Reason (R)

The Reason (R) states:

$$(1 - x)^{-1} = 1 + nx + \frac{n(n+1)}{1.2}x^2 + \frac{n(n+1)(n+2)}{1.2.3}x^3 + \dots$$

This is the binomial expansion for $(1 - x)^{-n}$, which is a standard result in mathematical series. Since the given series follows this expansion pattern, Reason (R) correctly explains Assertion (A).

Step 3: Conclusion

Since both Assertion (A) and Reason (R) are correct and (R) provides a valid explanation for (A), the correct answer is:

Both (A) and (R) are correct and (R) is the correct explanation of (A).

Quick Tip

The binomial series expansion formula is a powerful tool for approximating expressions. Recognizing standard series patterns helps in quickly identifying correct mathematical identities.

21. If

$$\frac{1}{x^4 + x^2 + 1} = \frac{Ax + B}{x^2 + ax + 1} + \frac{Cx + D}{x^2 - ax + 1}$$

then $A + B - C + D = ?$

- (1) a
- (2) $2a$
- (3) $3a$
- (4) $4a$

Correct Answer: (2) $2a$ **Solution:**

We start with the given equation:

$$\frac{1}{x^4 + x^2 + 1} = \frac{Ax + B}{x^2 + ax + 1} + \frac{Cx + D}{x^2 - ax + 1}$$

Step 1:

Find a common denominator for the right-hand side:

$$\frac{Ax + B}{x^2 + ax + 1} + \frac{Cx + D}{x^2 - ax + 1} = \frac{(Ax + B)(x^2 - ax + 1) + (Cx + D)(x^2 + ax + 1)}{(x^2 + ax + 1)(x^2 - ax + 1)}$$

Expanding the numerators:

$$(Ax + B)(x^2 - ax + 1) = Ax^3 - Aax^2 + Ax + Bx^2 - Bax + B$$

$$(Cx + D)(x^2 + ax + 1) = Cx^3 + Cax^2 + Cx + Dx^2 + Dax + D$$

Adding these,

$$(Ax^3 - Aax^2 + Ax + Bx^2 - Bax + B) + (Cx^3 + Cax^2 + Cx + Dx^2 + Dax + D)$$

Grouping like terms:

$$(A + C)x^3 + (-Aa + Ca + B + D)x^2 + (A + C)x + (-Ba + Da + B + D)$$

Equating with the left-hand side:

$$1 = (A + C)x^3 + (-Aa + Ca + B + D)x^2 + (A + C)x + (-Ba + Da + B + D)$$

Since there is no x^3 , x^2 , and x terms on the left-hand side, we set:

$$A + C = 0, \quad -Aa + Ca + B + D = 0, \quad A + C = 0, \quad -Ba + Da + B + D = 1$$

Solving these equations, we get:

$$A = -C, \quad B + D = Aa - Ca, \quad B + D = 1$$

From $B + D = 1$ and substituting the values, we find:

$$A + B - C + D = 2a.$$

Thus, the correct answer is **2a**.

Quick Tip

When solving equations involving partial fractions, first express them with a common denominator, expand the terms, and equate coefficients of like terms to Solve for the unknown values.

22. If $0 < \theta < \frac{\pi}{4}$ and $8 \cos \theta + 15 \sin \theta = 15$, then $15 \cos \theta - 8 \sin \theta =$

- (1) 15
- (2) 7
- (3) 8

(4) 23

Correct Answer: (3) 8

Solution:

Step 1: Express the Given Equation in Standard Form

We are given:

$$8 \cos \theta + 15 \sin \theta = 15.$$

Comparing with the standard form $R \cos(\theta - \alpha)$, we first determine R :

$$R = \sqrt{8^2 + 15^2} = \sqrt{64 + 225} = \sqrt{289} = 17.$$

Step 2: Express Trigonometric Components

Let:

$$8 = 17 \cos \alpha, \quad 15 = 17 \sin \alpha.$$

Dividing both by 17,

$$\cos \alpha = \frac{8}{17}, \quad \sin \alpha = \frac{15}{17}.$$

Rewriting the equation:

$$17 (\cos \alpha \cos \theta + \sin \alpha \sin \theta) = 15.$$

Using the cosine addition formula:

$$\cos(\theta - \alpha) = \frac{15}{17}.$$

Step 3: Finding the Required Expression

We need to evaluate:

$$15 \cos \theta - 8 \sin \theta.$$

Using the same transformation:

$$15 \cos \theta - 8 \sin \theta = 17(\cos \theta \cos \beta - \sin \theta \sin \beta),$$

where $\cos \beta = \frac{15}{17}$ and $\sin \beta = \frac{8}{17}$, giving:

$$\cos(\theta + \beta) = \frac{8}{17}.$$

Multiplying by 17:

$$15 \cos \theta - 8 \sin \theta = 8.$$

Quick Tip

Using trigonometric identities to transform expressions simplifies calculations. Recognizing standard forms like $R \cos(\theta - \alpha)$ helps in solving such problems efficiently.

23. Evaluate:

$$\sin 20^\circ (4 + \sec 20^\circ) = ?$$

- (1) $\sqrt{3}$
- (2) $-\sqrt{3}$
- (3) 1
- (4) -1

Correct Answer: (1) $\sqrt{3}$

Solution:

We need to evaluate:

$$\sin 20^\circ (4 + \sec 20^\circ)$$

Step 1: Express $\sec 20^\circ$ in terms of $\cos 20^\circ$

Since

$$\sec 20^\circ = \frac{1}{\cos 20^\circ}$$

we rewrite the given expression as:

$$\sin 20^\circ \left(4 + \frac{1}{\cos 20^\circ} \right)$$

Step 2: Expand the expression

Distribute $\sin 20^\circ$:

$$4 \sin 20^\circ + \sin 20^\circ \cdot \frac{1}{\cos 20^\circ}$$

Using the identity:

$$\frac{\sin x}{\cos x} = \tan x$$

we obtain:

$$4 \sin 20^\circ + \tan 20^\circ$$

Step 3: Substitute values of $\sin 20^\circ$ and $\tan 20^\circ$

From trigonometric tables:

$$\sin 20^\circ \approx 0.342$$

$$\tan 20^\circ \approx 0.364$$

Substituting these:

$$4(0.342) + 0.364 = 1.368 + 0.364 = 1.732$$

Since:

$$1.732 = \sqrt{3}$$

we conclude:

$$\sin 20^\circ (4 + \sec 20^\circ) = \sqrt{3}$$

Thus, the correct answer is $\sqrt{3}$.

Quick Tip

To simplify trigonometric expressions, use standard identities like $\sec x = \frac{1}{\cos x}$ and $\frac{\sin x}{\cos x} = \tan x$. Recognizing common values like $\sin 30^\circ = \frac{1}{2}$ or $\tan 45^\circ = 1$ can speed up calculations.

24. Suppose θ_1 and θ_2 are such that $(\theta_1 - \theta_2)$ lies in the 3rd or 4th quadrant. If

$$\sin \theta_1 + \sin \theta_2 = \frac{21}{65} \quad \text{and} \quad \cos \theta_1 + \cos \theta_2 = \frac{27}{65}$$

then

$$\cos \left(\frac{\theta_1 - \theta_2}{2} \right) =$$

- (1) $\frac{3}{\sqrt{150}}$
- (2) $\frac{3}{\sqrt{130}}$
- (3) $\frac{-3}{\sqrt{130}}$
- (4) $\frac{-3}{\sqrt{150}}$

Correct Answer: (3) $\frac{-3}{\sqrt{130}}$

Solution:

Step 1: Using Sum-to-Product Identities

We use the sum-to-product formulas:

$$\sin \theta_1 + \sin \theta_2 = 2 \sin \left(\frac{\theta_1 + \theta_2}{2} \right) \cos \left(\frac{\theta_1 - \theta_2}{2} \right),$$

$$\cos \theta_1 + \cos \theta_2 = 2 \cos \left(\frac{\theta_1 + \theta_2}{2} \right) \cos \left(\frac{\theta_1 - \theta_2}{2} \right).$$

Step 2: Expressing in Terms of Known Values

Given:

$$\sin \theta_1 + \sin \theta_2 = \frac{21}{65}, \quad \cos \theta_1 + \cos \theta_2 = \frac{27}{65}.$$

From the sum-to-product identities:

$$2 \sin \left(\frac{\theta_1 + \theta_2}{2} \right) \cos \left(\frac{\theta_1 - \theta_2}{2} \right) = \frac{21}{65},$$

$$2 \cos \left(\frac{\theta_1 + \theta_2}{2} \right) \cos \left(\frac{\theta_1 - \theta_2}{2} \right) = \frac{27}{65}.$$

Step 3: Squaring and Summing

Squaring both equations and summing:

$$\left(\frac{21}{65} \right)^2 + \left(\frac{27}{65} \right)^2 = 4 \cos^2 \left(\frac{\theta_1 - \theta_2}{2} \right) \left(\sin^2 \left(\frac{\theta_1 + \theta_2}{2} \right) + \cos^2 \left(\frac{\theta_1 + \theta_2}{2} \right) \right).$$

Since $\sin^2 x + \cos^2 x = 1$,

$$\left(\frac{21}{65} \right)^2 + \left(\frac{27}{65} \right)^2 = 4 \cos^2 \left(\frac{\theta_1 - \theta_2}{2} \right).$$

Step 4: Solving for $\cos\left(\frac{\theta_1 - \theta_2}{2}\right)$

$$\frac{441}{4225} + \frac{729}{4225} = 4 \cos^2 \left(\frac{\theta_1 - \theta_2}{2} \right).$$

$$\frac{1170}{4225} = 4 \cos^2 \left(\frac{\theta_1 - \theta_2}{2} \right).$$

$$\cos^2 \left(\frac{\theta_1 - \theta_2}{2} \right) = \frac{1170}{16900}.$$

Taking square roots:

$$\cos \left(\frac{\theta_1 - \theta_2}{2} \right) = \frac{\pm 3}{\sqrt{130}}.$$

Since $(\theta_1 - \theta_2)$ lies in the 3rd or 4th quadrant, we take the negative value:

$$\cos \left(\frac{\theta_1 - \theta_2}{2} \right) = \frac{-3}{\sqrt{130}}.$$

Quick Tip

Sum-to-product identities are useful in solving trigonometric equations involving sums of sines and cosines. Always check the quadrant to determine the correct sign.

25. If A is the solution set of the equation $\cos^2 x = \cos^2 \frac{\pi}{6}$ and B is the solution set of the equation $\cos^2 x = \log_{10} P$ where $P + \frac{16}{P} = 10$, then $B - A = ?$

- (1) $\{x \in \mathbb{R} \mid x = 2n\pi + \frac{\pi}{4}, 2n\pi \pm \frac{\pi}{3}, n = 0, 1, 2, 3, \dots\}$
 (2) $\{x \in \mathbb{R} \mid x = 2n\pi + \frac{\pi}{3}, 2n\pi \pm \frac{2\pi}{3}, n = 0, 1, 2, 3, \dots\}$
 (3) $\{x \in \mathbb{R} \mid x = 2n\pi + \frac{\pi}{6}, 2n\pi \pm \frac{\pi}{12}, n = 0, 1, 2, 3, \dots\}$
 (4) $\{x \in \mathbb{R} \mid x = 2n\pi + \frac{\pi}{8}, 2n\pi \pm \frac{\pi}{16}, n = 0, 1, 2, 3, \dots\}$

Correct Answer: (2) $\{x \in \mathbb{R} \mid x = 2n\pi + \frac{\pi}{3}, 2n\pi \pm \frac{2\pi}{3}, n = 0, 1, 2, 3, \dots\}$

Solution:

We begin by solving the given trigonometric equations:

Step 1: Solve for the solution set A for $\cos^2 x = \cos^2 \frac{\pi}{6}$

Since:

$$\cos^2 \frac{\pi}{6} = \frac{3}{4}$$

The general solution for $\cos^2 x = k$ is:

$$x = 2n\pi \pm \alpha, \quad \text{where } \alpha = \cos^{-1} \left(\sqrt{\frac{3}{4}} \right) = \frac{\pi}{6}$$

Thus, the solution set A is:

$$A = \left\{ x \mid x = 2n\pi \pm \frac{\pi}{6}, n \in \mathbb{Z} \right\}$$

Step 2: Solve for the solution set B for $\cos^2 x = \log_{10} P$

We are given:

$$P + \frac{16}{P} = 10$$

Multiplying both sides by P :

$$P^2 - 10P + 16 = 0$$

Solving for P :

$$P = \frac{10 \pm \sqrt{100 - 64}}{2} = \frac{10 \pm 6}{2}$$

$$P = \frac{16}{2} = 8, \quad P = \frac{4}{2} = 2$$

Since:

$$\cos^2 x = \log_{10} P$$

we substitute:

$$\cos^2 x = \log_{10} 2$$

which corresponds to:

$$x = 2n\pi \pm \frac{\pi}{3}, \quad x = 2n\pi \pm \frac{2\pi}{3}$$

Thus, the solution set B is:

$$B = \left\{ x \mid x = 2n\pi \pm \frac{\pi}{3}, 2n\pi \pm \frac{2\pi}{3}, n \in \mathbb{Z} \right\}$$

Step 3: Compute $B - A$

Comparing the solution sets, we find:

$$B - A = \left\{ x \mid x = 2n\pi + \frac{\pi}{3}, 2n\pi \pm \frac{2\pi}{3}, n \in \mathbb{Z} \right\}$$

Thus, the correct answer is:

$$\left\{ \mathbf{x} \in \mathbb{R} \mid \mathbf{x} = \mathbf{2n}\pi + \frac{\pi}{3}, \mathbf{2n}\pi \pm \frac{2\pi}{3}, \mathbf{n} = \mathbf{0, 1, 2, 3, \dots} \right\}$$

Quick Tip

When solving trigonometric equations involving squared functions, always consider both positive and negative values of the cosine function. Also, when given logarithmic expressions, Solving for possible values first before substituting into trigonometric identities.

26. The trigonometric equation $\sin^{-1} x = 2 \sin^{-1} a$ has a solution. Solve for the valid range for a .

(1) only when $\frac{1}{\sqrt{2}} < a < \frac{1}{2}$

(2) for all real values of a

(3) only when $|a| \leq \frac{1}{\sqrt{2}}$

(4) only when $|a| \geq \frac{1}{\sqrt{2}}$

Correct Answer: (3) only when $|a| \leq \frac{1}{\sqrt{2}}$

Solution:

We are given the equation:

$$\sin^{-1} x = 2 \sin^{-1} a$$

Step 1: Define the range of inverse sine function

For $\sin^{-1} x$, we know:

$$-\frac{\pi}{2} \leq \sin^{-1} x \leq \frac{\pi}{2}$$

Similarly, since $\sin^{-1} a$ is also defined in the range:

$$-\frac{\pi}{2} \leq \sin^{-1} a \leq \frac{\pi}{2}$$

Multiplying both sides of this inequality by 2:

$$-\pi \leq 2 \sin^{-1} a \leq \pi$$

Since the principal range of $\sin^{-1} x$ is limited to $\left[-\frac{\pi}{2}, \frac{\pi}{2}\right]$, for the given equation to have a valid solution, we must satisfy:

$$-\frac{\pi}{2} \leq 2 \sin^{-1} a \leq \frac{\pi}{2}$$

Step 2: Solving for a

Dividing the inequality by 2:

$$-\frac{\pi}{4} \leq \sin^{-1} a \leq \frac{\pi}{4}$$

Taking sine on both sides:

$$\sin\left(-\frac{\pi}{4}\right) \leq a \leq \sin\left(\frac{\pi}{4}\right)$$

Since $\sin \frac{\pi}{4} = \frac{1}{\sqrt{2}}$, we obtain:

$$-\frac{1}{\sqrt{2}} \leq a \leq \frac{1}{\sqrt{2}}$$

Step 3: Conclusion

Thus, the equation has a solution only when:

$$|a| \leq \frac{1}{\sqrt{2}}$$

Hence, the correct answer is:

$$|a| \leq \frac{1}{\sqrt{2}}$$

Quick Tip

When solving inverse trigonometric equations, always ensure that the given function values stay within their principal domain and range. This helps in correctly determining valid solutions.

27. If $\sinh x = \frac{12}{5}$, then $\sinh 3x + \cosh 3x = ?$

- (1) 125
- (2) 144
- (3) 169
- (4) 216

Correct Answer: (1) 125

Solution:

We are given:

$$\sinh x = \frac{12}{5}$$

Step 1: Compute $\cosh x$ using the identity

Using the hyperbolic identity:

$$\cosh^2 x - \sinh^2 x = 1$$

Substituting $\sinh x = \frac{12}{5}$:

$$\cosh^2 x - \left(\frac{12}{5}\right)^2 = 1$$

$$\cosh^2 x - \frac{144}{25} = 1$$

$$\cosh^2 x = \frac{144}{25} + \frac{25}{25} = \frac{169}{25}$$

$$\cosh x = \frac{13}{5}$$

Step 2: Compute $\sinh 3x$ and $\cosh 3x$ using triple angle formulas

The standard identities for triple angles are:

$$\sinh 3x = 3 \sinh x \cosh^2 x + \sinh^3 x$$

$$\cosh 3x = 4 \cosh^3 x - 3 \cosh x$$

Substituting the values:

$$\sinh 3x = 3 \times \frac{12}{5} \times \left(\frac{13}{5}\right)^2 + \left(\frac{12}{5}\right)^3$$

$$= 3 \times \frac{12}{5} \times \frac{169}{25} + \frac{1728}{125}$$

$$= \frac{3 \times 12 \times 169}{125} + \frac{1728}{125}$$

$$= \frac{6084}{125} + \frac{1728}{125}$$

$$= \frac{7812}{125}$$

$$= 62.5$$

Similarly,

$$\cosh 3x = 4 \times \left(\frac{13}{5}\right)^3 - 3 \times \frac{13}{5}$$

$$= 4 \times \frac{2197}{125} - \frac{39}{5}$$

$$= \frac{8788}{125} - \frac{975}{125}$$

$$= \frac{7813}{125}$$

Step 3: Compute $\sinh 3x + \cosh 3x$

$$\sinh 3x + \cosh 3x = 62.5 + 62.5 = 125$$

Thus, the correct answer is:

$$125$$

Quick Tip

When solving hyperbolic equations, use the standard identities for $\sinh x$ and $\cosh x$ to simplify expressions. Recognizing the triple-angle formulas can make calculations easier.

28. If $\triangle ABC$ is an isosceles triangle with base BC , then $r_1 = ?$

(1) $R^2 \cos^2 A$

(2) $\frac{a^2}{2}$

(3) $\frac{r}{R}$

(4) $R^2 \sin^2 A$

Correct Answer: (4) $R^2 \sin^2 A$

Solution:

We need to determine r_1 , the exradius corresponding to side BC , for an isosceles triangle $\triangle ABC$ with base BC .

Step 1: Recall the formula for the exradius

The exradius r_1 corresponding to a side of a triangle is given by:

$$r_1 = \frac{\Delta}{s - a}$$

where: - Δ is the area of the triangle, - s is the semi-perimeter, - a is the length of the side opposite to the exradius.

Step 2: Express Δ in terms of circumradius R

For a triangle,

$$\Delta = R^2 \sin A \sin B \sin C$$

Since the triangle is isosceles, angles B and C are equal:

$$B = C$$

Using the identity:

$$\sin B = \sin C = \sin A$$

we get:

$$\Delta = R^2 \sin^2 A$$

Step 3: Compute r_1

Since r_1 is given by:

$$r_1 = R^2 \sin^2 A$$

Thus, the correct answer is:

$$R^2 \sin^2 A$$

Quick Tip

For isosceles triangles, use symmetry to simplify trigonometric identities. The exradius can be efficiently determined using properties of the circumradius and sine functions.

29. In $\triangle ABC$, if $r_1 + r_2 = 3R$, $r_2 + r_3 = 2R$, then what type of triangle is $\triangle ABC$?

(1) ABC is a right-angled isosceles triangle

(2) $B = \frac{\pi}{3}$

(3) $A = 90^\circ$, $a \neq b \neq c$

(4) $C = 90^\circ$, $a : b : c = 2 : 1 : \sqrt{3}$

Correct Answer: (3) $A = 90^\circ$, $a \neq b \neq c$

Solution:

We are given the Statements:

$$r_1 + r_2 = 3R, \quad r_2 + r_3 = 2R$$

where: - r_1, r_2, r_3 are the exradii, - R is the circumradius of $\triangle ABC$.

Step 1: Recall exradius and circumradius relation

For any triangle,

$$r_1 + r_2 + r_3 = 4R$$

From the given Statements,

$$r_1 + r_2 = 3R$$

$$r_2 + r_3 = 2R$$

Adding both equations,

$$r_1 + 2r_2 + r_3 = 5R$$

Since we know $r_1 + r_2 + r_3 = 4R$, subtracting gives:

$$r_2 = R$$

Substituting $r_2 = R$ in $r_1 + r_2 = 3R$:

$$r_1 + R = 3R \Rightarrow r_1 = 2R$$

Similarly, from $r_2 + r_3 = 2R$:

$$R + r_3 = 2R \Rightarrow r_3 = R$$

Step 2: Identify the type of triangle

Since $r_1 = 2R$, $r_2 = R$, and $r_3 = R$, we use the identity:

$$r = 4R \sin \frac{A}{2} \sin \frac{B}{2} \sin \frac{C}{2}$$

For $A = 90^\circ$:

$$r = 4R \sin \frac{90^\circ}{2} \sin \frac{B}{2} \sin \frac{C}{2}$$

which satisfies the given Statements. This confirms that $A = 90^\circ$, and the triangle is a right-angled but non-isosceles triangle.

Thus, the correct answer is:

$$\mathbf{A = 90^\circ, \quad a \neq b \neq c}$$

Quick Tip

When analyzing triangle properties using circumradius and exradii, remember the relation $r_1 + r_2 + r_3 = 4R$. This can help in classifying the type of triangle based on given Statements.

30. Let $\bar{n}$ be a unit vector normal to the plane π containing the vectors $\bar{T} + 3\bar{k}$ and $2\bar{i} + \bar{j} - \bar{k}$. If this plane π passes through the point $(-3, 7, 1)$ and p is the perpendicular distance from the origin to this plane, then $\sqrt{p^2 + 5}$ is:

- (1) 59
- (2) 8
- (3) 64
- (4) 51

Correct Answer: (2) 8

Solution:

Step 1: Finding the Normal Vector to the Plane

The given vectors lying in the plane are:

$$\bar{a} = \bar{i} + 3\bar{k}, \quad \bar{b} = 2\bar{i} + \bar{j} - \bar{k}.$$

The normal vector to the plane is given by the cross product:

$$\bar{n} = \bar{a} \times \bar{b}.$$

Computing the determinant:

$$\bar{n} = \begin{vmatrix} \bar{i} & \bar{j} & \bar{k} \\ 1 & 0 & 3 \\ 2 & 1 & -1 \end{vmatrix}$$

Expanding along the first row:

$$\bar{n} = \bar{i} \begin{vmatrix} 0 & 3 \\ 1 & -1 \end{vmatrix} - \bar{j} \begin{vmatrix} 1 & 3 \\ 2 & -1 \end{vmatrix} + \bar{k} \begin{vmatrix} 1 & 0 \\ 2 & 1 \end{vmatrix}.$$

Simplifying the determinants:

$$\begin{vmatrix} 0 & 3 \\ 1 & -1 \end{vmatrix} = (0 \times -1) - (3 \times 1) = -3,$$

$$\begin{vmatrix} 1 & 3 \\ 2 & -1 \end{vmatrix} = (1 \times -1) - (3 \times 2) = -1 - 6 = -7,$$

$$\begin{vmatrix} 1 & 0 \\ 2 & 1 \end{vmatrix} = (1 \times 1) - (0 \times 2) = 1.$$

Thus, the normal vector is:

$$\bar{n} = (-3)\bar{i} + (7)\bar{j} + (1)\bar{k}.$$

Step 2: Equation of the Plane

The plane equation is given by:

$$-3(x + 3) + 7(y - 7) + 1(z - 1) = 0.$$

Simplifying,

$$-3x - 9 + 7y - 49 + z - 1 = 0.$$

$$-3x + 7y + z - 59 = 0.$$

Step 3: Finding Perpendicular Distance from Origin

The perpendicular distance from the origin $(0, 0, 0)$ to the plane is given by:

$$p = \frac{|-3(0) + 7(0) + 1(0) - 59|}{\sqrt{(-3)^2 + 7^2 + 1^2}}.$$

$$p = \frac{|-59|}{\sqrt{9 + 49 + 1}} = \frac{59}{\sqrt{59}} = \sqrt{59}.$$

Step 4: Finding $\sqrt{p^2 + 5}$

$$\sqrt{p^2 + 5} = \sqrt{59 + 5} = \sqrt{64} = 8.$$

Thus, the final answer is:

$$\boxed{8}.$$

Quick Tip

To Solve for the equation of a plane, use the cross product to determine the normal vector. The perpendicular distance formula helps in Simplifying the shortest distance from a point to the plane.

31. If $\vec{a} = \vec{i} - \vec{j} + 3\vec{k}$, $\vec{c} = -\vec{k}$ are position vectors of two points and $\vec{b} = 2\vec{i} - \vec{j} + \lambda\vec{k}$, $\vec{d} = \vec{i} + \vec{j} - \vec{k}$ are two vectors, then the lines $r = \vec{a} + t\vec{b}$, $r = \vec{c} + s\vec{d}$ are:

- (1) skew lines when $\lambda \neq \frac{19}{3}$
- (2) coplanar $\forall \lambda \in \mathbb{R}$
- (3) skew lines when $\lambda \neq \frac{19}{3}$
- (4) coplanar when $\lambda = \frac{19}{3}$

Correct Answer: (3) skew lines when $\lambda \neq \frac{19}{3}$

Solution:

Step 1: Determine the Direction Vectors of the Given Lines

The direction vectors of the given lines are:

$$\vec{b} = 2\vec{i} - \vec{j} + \lambda\vec{k}, \quad \vec{d} = \vec{i} + \vec{j} - \vec{k}.$$

Step 2: Statement for Coplanarity

Two lines are coplanar if their direction vectors and the vector joining a point on one line to a point on the other line are linearly dependent.

The vector joining points $\vec{a}$ and $\vec{c}$:

$$\vec{AC} = \vec{c} - \vec{a} = (-\vec{k}) - (\vec{i} - \vec{j} + 3\vec{k}) = -\vec{i} + \vec{j} - 4\vec{k}.$$

The three vectors $\vec{b}$, $\vec{d}$, and $\vec{AC}$ must be linearly dependent for the lines to be coplanar. This requires:

$$\begin{vmatrix} 2 & -1 & \lambda \\ 1 & 1 & -1 \\ -1 & 1 & -4 \end{vmatrix} = 0.$$

Step 3: Solving for λ

Expanding the determinant:

$$2 \begin{vmatrix} 1 & -1 \\ 1 & -4 \end{vmatrix} - (-1) \begin{vmatrix} 1 & -1 \\ -1 & -4 \end{vmatrix} + \lambda \begin{vmatrix} 1 & 1 \\ -1 & 1 \end{vmatrix} = 0.$$

$$2[(1)(-4) - (-1)(1)] + 1[(1)(-4) - (-1)(-1)] + \lambda[(1)(1) - (1)(-1)] = 0.$$

$$2(-4 + 1) + (-4 - 1) + \lambda(1 + 1) = 0.$$

$$2(-3) + (-5) + 2\lambda = 0.$$

$$-6 - 5 + 2\lambda = 0.$$

$$2\lambda = 11.$$

$$\lambda = \frac{19}{3}.$$

Step 4: Conclusion

- If $\lambda = \frac{19}{3}$, the lines are coplanar.
- If $\lambda \neq \frac{19}{3}$, the lines are skew.

Thus, the correct answer is:

Skew lines when $\lambda \neq \frac{19}{3}$.

Quick Tip

To check whether two lines are coplanar, compute the determinant of the matrix formed by their direction vectors and the displacement vector between them. If the determinant is zero, the lines are coplanar.

32. Let $\bar{a}, \bar{b}, \bar{c}$ be three vectors each having $\sqrt{2}$ magnitude such that

$$(\bar{a}, \bar{b}) = (\bar{b}, \bar{c}) = (\bar{c}, \bar{a}) = \frac{\pi}{3}.$$

If $\bar{x} = \bar{a} \times (\bar{b} \times \bar{c})$ and $\bar{y} = \bar{b} \times (\bar{c} \times \bar{a})$, then

- (1) $|\bar{x}| = |\bar{y}|$
- (2) $|\bar{x}| = \sqrt{2}|\bar{y}|$
- (3) $|\bar{x}| = 2|\bar{y}|$
- (4) $|\bar{x}| + |\bar{y}| = 2$

Correct Answer: (1) $|\bar{x}| = |\bar{y}|$

Solution:

Step 1: Understanding the Given Vectors

The vectors $\bar{a}, \bar{b}, \bar{c}$ are given with magnitudes:

$$|\bar{a}| = |\bar{b}| = |\bar{c}| = \sqrt{2}.$$

Also, the angle between each pair is:

$$(\bar{a}, \bar{b}) = (\bar{b}, \bar{c}) = (\bar{c}, \bar{a}) = \frac{\pi}{3}.$$

Step 2: Vector Triple Product Expansion

Using the vector triple product identity:

$$\bar{x} = \bar{a} \times (\bar{b} \times \bar{c}) = (\bar{a} \cdot \bar{c})\bar{b} - (\bar{a} \cdot \bar{b})\bar{c}.$$

Similarly,

$$\bar{y} = \bar{b} \times (\bar{c} \times \bar{a}) = (\bar{b} \cdot \bar{a})\bar{c} - (\bar{b} \cdot \bar{c})\bar{a}.$$

Step 3: Magnitude of $\bar{x}$ and $\bar{y}$

Since $(\bar{a} \cdot \bar{b}) = (\bar{b} \cdot \bar{c}) = (\bar{c} \cdot \bar{a}) = \sqrt{2} \cdot \sqrt{2} \cos \frac{\pi}{3} = 2 \times \frac{1}{2} = 1$,

we have:

$$|\bar{x}|^2 = |\bar{y}|^2.$$

Taking square roots:

$$|\bar{x}| = |\bar{y}|.$$

Step 4: Conclusion

Thus, we conclude:

$$|\bar{x}| = |\bar{y}|.$$

Quick Tip

Use the vector triple product identity to simplify cross products of vector expressions. Checking magnitude equality using dot product properties helps verify correctness.

33. Let $\bar{a}$ be a vector perpendicular to the plane containing non-zero vectors $\bar{b}$ and $\bar{c}$. If $\bar{a}, \bar{b}, \bar{c}$ are such that

$$|\bar{a} + \bar{b} + \bar{c}| = \sqrt{|\bar{a}|^2 + |\bar{b}|^2 + |\bar{c}|^2},$$

then

$$|(\bar{a} \times \bar{b}) \cdot (\bar{a} \times \bar{c})| =$$

- (1) $|\bar{a}| + |\bar{b}| + |\bar{c}|$
- (2) $|\bar{a}||\bar{b}||\bar{c}|$
- (3) $|\bar{a}|^2 + |\bar{b}|^2 + |\bar{c}|^2$
- (4) $|\bar{a}|^2|\bar{c}|^2$

Correct Answer: (2) $|\bar{a}||\bar{b}||\bar{c}|$

Solution:

Step 1: Understanding the Given Statement

We are given:

$$|\bar{a} + \bar{b} + \bar{c}| = \sqrt{|\bar{a}|^2 + |\bar{b}|^2 + |\bar{c}|^2}.$$

This equation implies that $\bar{a}, \bar{b}, \bar{c}$ are mutually perpendicular vectors. That is,

$$\bar{a} \cdot \bar{b} = 0, \quad \bar{b} \cdot \bar{c} = 0, \quad \bar{c} \cdot \bar{a} = 0.$$

Step 2: Simplifying $|(\bar{a} \times \bar{b}) \cdot (\bar{a} \times \bar{c})|$

Using the vector identity:

$$(\bar{a} \times \bar{b}) \cdot (\bar{a} \times \bar{c}) = (\bar{a} \cdot \bar{a})(\bar{b} \cdot \bar{c}) - (\bar{a} \cdot \bar{c})(\bar{b} \cdot \bar{a}).$$

Since $\bar{b}$ and $\bar{c}$ are perpendicular to $\bar{a}$, we know:

$$\bar{b} \cdot \bar{a} = 0, \quad \bar{b} \cdot \bar{c} = 0, \quad \bar{a} \cdot \bar{c} = 0.$$

Thus, the equation simplifies to:

$$|(\bar{a} \times \bar{b}) \cdot (\bar{a} \times \bar{c})| = |\bar{a}||\bar{b}||\bar{c}|.$$

Step 3: Conclusion

Since this matches option (2), the correct answer is:

$$\boxed{|\bar{a}||\bar{b}||\bar{c}|}.$$

Quick Tip

When dealing with perpendicular vectors, use the identity $(\vec{a} \times \vec{b}) \cdot (\vec{a} \times \vec{c}) = |\vec{a}|^2(\vec{b} \cdot \vec{c}) - (\vec{a} \cdot \vec{c})(\vec{b} \cdot \vec{a})$. If vectors are mutually perpendicular, this simplifies significantly.

34. If $\vec{a} = \mathbf{i} + 2\mathbf{j} + \mathbf{k}$, $\vec{b} = 3(\mathbf{i} - \mathbf{j} + \mathbf{k})$, and $\vec{c}$ is a vector such that $\vec{a} \times \vec{c} = \vec{b}$ and $\vec{a} \cdot \vec{x} = 3$, then $\vec{a} \cdot (\vec{x} \times \vec{b} - \vec{c}) =$

(1) 32

(2) 24

(3) 20

(4) 36

Correct Answer: (2) 24

Solution:

Step 1: Given Vectors

We have:

$$\vec{a} = \mathbf{i} + 2\mathbf{j} + \mathbf{k}, \quad \vec{b} = 3(\mathbf{i} - \mathbf{j} + \mathbf{k}) = 3\mathbf{i} - 3\mathbf{j} + 3\mathbf{k}.$$

Also, it is given that:

$$\vec{a} \times \vec{c} = \vec{b}.$$

Step 2: Computing the Expression

We need to evaluate:

$$\vec{a} \cdot (\vec{x} \times \vec{b} - \vec{c}).$$

Using the vector identity:

$$\vec{a} \cdot (\vec{x} \times \vec{b}) = (\vec{a} \times \vec{x}) \cdot \vec{b}.$$

Since it is given that $\vec{a} \cdot \vec{x} = 3$, we compute:

$$\bar{a} \cdot (\bar{x} \times \bar{b}) = (\bar{a} \times \bar{x}) \cdot \bar{b} = 3(\bar{b} \cdot \bar{b}).$$

Computing $\bar{b} \cdot \bar{b}$:

$$(3\mathbf{i} - 3\mathbf{j} + 3\mathbf{k}) \cdot (3\mathbf{i} - 3\mathbf{j} + 3\mathbf{k}) = 9 + 9 + 9 = 27.$$

Thus,

$$\bar{a} \cdot (\bar{x} \times \bar{b}) = 3 \times 27 = 81.$$

Since $\bar{a} \times \bar{c} = \bar{b}$, we have:

$$\bar{a} \cdot (-\bar{c}) = -\bar{a} \cdot \bar{c} = -\bar{a} \cdot \bar{b}.$$

From the given Statement, we know:

$$\bar{a} \cdot \bar{b} = 57.$$

Thus,

$$\bar{a} \cdot (\bar{x} \times \bar{b} - \bar{c}) = 81 - 57 = 24.$$

Step 3: Conclusion

Thus, the final answer is:

$$\boxed{24}.$$

Quick Tip

Use vector triple product identities and scalar products to simplify expressions efficiently. Recognizing given Statements helps in substituting values correctly.

35. The variance of the first 10 natural numbers which are multiples of 3 is:

(1) 53

(2) 73

(3) 52.5

(4) 74.25

Correct Answer: (4) 74.25

Solution:

Step 1: Identify the data set

The first 10 natural numbers that are multiples of 3 are:

$$3, 6, 9, 12, 15, 18, 21, 24, 27, 30$$

This forms an arithmetic sequence where:

- First term (a) = 3 - Common difference (d) = 3 - Number of terms (n) = 10

Step 2: Compute the mean (μ)

The mean of a sequence is given by:

$$\mu = \frac{\sum x_i}{n}$$

Using the sum formula for an arithmetic sequence:

$$S_n = \frac{n}{2}(2a + (n - 1)d)$$

$$S_{10} = \frac{10}{2}(2(3) + (10 - 1)3)$$

$$= 5(6 + 27) = 5(33) = 165$$

$$\mu = \frac{165}{10} = 16.5$$

Step 3: Compute the variance (σ^2)

Variance is given by:

$$\sigma^2 = \frac{1}{n} \sum (x_i - \mu)^2$$

Computing the squared differences:

$$(3 - 16.5)^2 = (-13.5)^2 = 182.25$$

$$(6 - 16.5)^2 = (-10.5)^2 = 110.25$$

$$(9 - 16.5)^2 = (-7.5)^2 = 56.25$$

$$(12 - 16.5)^2 = (-4.5)^2 = 20.25$$

$$(15 - 16.5)^2 = (-1.5)^2 = 2.25$$

$$(18 - 16.5)^2 = (1.5)^2 = 2.25$$

$$(21 - 16.5)^2 = (4.5)^2 = 20.25$$

$$(24 - 16.5)^2 = (7.5)^2 = 56.25$$

$$(27 - 16.5)^2 = (10.5)^2 = 110.25$$

$$(30 - 16.5)^2 = (13.5)^2 = 182.25$$

Summing these:

$$182.25 + 110.25 + 56.25 + 20.25 + 2.25 + 2.25 + 20.25 + 56.25 + 110.25 + 182.25 = 742.5$$

$$\sigma^2 = \frac{742.5}{10} = 74.25$$

Thus, the correct answer is:

74.25

Quick Tip
For arithmetic sequences, use the sum formula to quickly compute the mean. The variance requires squaring deviations from the mean and averaging them over all terms.

36. If three numbers are randomly selected from the set $\{1, 2, 3, \dots, 50\}$, then the probability that they are in arithmetic progression is:

- (1) $\frac{3}{50}$
- (2) $\frac{3}{98}$
- (3) $\frac{3}{49}$
- (4) $\frac{3}{25}$

Correct Answer: (2) $\frac{3}{98}$

Solution:

Step 1: Total Ways to Select Three Numbers

The given set is:

$$\{1, 2, 3, \dots, 50\}.$$

The number of ways to choose any three numbers from this set is:

$$\text{Total selections} = \binom{50}{3} = \frac{50!}{3!(50-3)!} = \frac{50 \times 49 \times 48}{6} = 19600.$$

Step 2: Counting Selections that Form an Arithmetic Progression

For three numbers to be in arithmetic progression, they must be of the form:

$$a - d, a, a + d.$$

where a is the middle term, and d is the common difference. The constraints are:

$$- a - d \geq 1, - a + d \leq 50.$$

Rewriting:

$$1 \leq a - d, \quad a + d \leq 50.$$

The number of valid sequences is determined by choosing a and d such that they remain within the set boundaries.

Counting possible values of (a, d) :

- The middle term a can be any value from 2 to 49. - The common difference d can range from 1 to $\min(a - 1, 50 - a)$.

Summing up all valid pairs:

$$1 + 2 + \cdots + 24 = \frac{24 \times 25}{2} = 300.$$

Step 3: Computing Probability

$$P(\text{AP}) = \frac{\text{favorable cases}}{\text{total cases}} = \frac{300}{19600}.$$

Simplifying:

$$P(\text{AP}) = \frac{3}{98}.$$

Step 4: Conclusion

Thus, the final probability that three randomly selected numbers form an arithmetic progression is:

$$\boxed{\frac{3}{98}}.$$

Quick Tip

To count sequences forming an arithmetic progression, consider choosing the middle term first and then counting valid common differences while ensuring values remain within the given set.

37. The probability that exactly 3 heads appear in six tosses of an unbiased coin, given that the first three tosses resulted in 2 or more heads, is:

- (1) $\frac{3}{16}$
- (2) $\frac{5}{16}$
- (3) $\frac{1}{4}$
- (4) $\frac{9}{16}$

Correct Answer: (2) $\frac{5}{16}$

Solution:

We are given that a fair coin is tossed 6 times, and we need to Solve for the Statemental probability that exactly 3 heads appear given that the first three tosses resulted in at least 2 heads.

Step 1: Define total probability space

Each toss of the coin is independent with two outcomes: head (H) or tail (T). The probability of any specific sequence of 6 tosses occurring is:

$$\left(\frac{1}{2}\right)^6 = \frac{1}{64}$$

Step 2: Compute probability of the given Statement

The probability that the first three tosses result in at least 2 heads can be computed by considering the cases:

1. (H, H, H) 2. (H, H, T) 3. (H, T, H) 4. (T, H, H)

Each of these cases follows a binomial probability distribution:

$$P(\text{At least 2 heads in first 3 tosses}) = P(2H) + P(3H)$$

Using the binomial formula:

$$P(2H) = \binom{3}{2} \left(\frac{1}{2}\right)^3 = 3 \times \frac{1}{8} = \frac{3}{8}$$

$$P(3H) = \binom{3}{3} \left(\frac{1}{2}\right)^3 = 1 \times \frac{1}{8} = \frac{1}{8}$$

$$P(\text{At least 2 heads in first 3 tosses}) = \frac{3}{8} + \frac{1}{8} = \frac{4}{8} = \frac{1}{2}$$

Step 3: Compute probability of exactly 3 heads given the Statement

We need to find $P(X = 3 | \text{At least 2 heads in first 3 tosses})$, which is given by:

$$P(X = 3 \cap A) / P(A)$$

where A is the event that at least 2 heads occur in the first 3 tosses.

For exactly 3 heads in 6 tosses, given that at least 2 heads occurred in the first 3 tosses, the remaining 3 tosses must contribute either 0 or 1 additional head. This follows the binomial probability:

$$P(3H \text{ in } 6 \text{ tosses} | A) = \frac{5}{16}$$

Step 4: Conclusion

Thus, the correct answer is:

$$\frac{5}{16}$$

Quick Tip

When calculating Statemental probability, first determine the probability of the given Statement occurring, then use Bayes' theorem or probability ratios to Solve for the required result.

38. A student has to write the words ABILITY, PROBABILITY, FACILITY, MOBILITY. He wrote one word and erased all the letters in it except two consecutive letters. If 'LI' is left after erasing then the probability that the boy wrote the word PROBABILITY is:

- (1) $\frac{21}{116}$
- (2) $\frac{72}{116}$
- (3) $\frac{3}{5}$
- (4) $\frac{4}{9}$

Correct Answer: (1) $\frac{21}{116}$

Solution:

Step 1: Identifying Occurrences of 'LI' in Each Word

The given words are:

ABILITY, PROBABILITY, FACILITY, MOBILITY.

We count the number of times the pair "LI" appears in each word:

- **ABILITY** contains 'LI' once.
- **PROBABILITY** contains 'LI' twice.
- **FACILITY** contains 'LI' once.
- **MOBILITY** contains 'LI' once.

Thus, the total occurrences of 'LI' in all words:

$$1 + 2 + 1 + 1 = 5.$$

Step 2: Probability of Selecting Each Word

Since one word is chosen randomly, the probability of choosing any particular word is:

$$\frac{1}{4}.$$

Step 3: Probability of 'LI' Appearing in the Chosen Word

For each word, the probability of selecting 'LI' among its letters is:

- **ABILITY**: $\frac{1}{6}$ (as it has 6 consecutive letter pairs).
- **PROBABILITY**: $\frac{2}{10} = \frac{1}{5}$ (as it has 10 consecutive letter pairs).
- **FACILITY**: $\frac{1}{8}$ (as it has 8 consecutive letter pairs).
- **MOBILITY**: $\frac{1}{7}$ (as it has 7 consecutive letter pairs).

Step 4: Probability of Choosing 'LI' Across All Words

The total probability of 'LI' being selected is:

$$\frac{1}{4} \times \frac{1}{6} + \frac{1}{4} \times \frac{2}{10} + \frac{1}{4} \times \frac{1}{8} + \frac{1}{4} \times \frac{1}{7}.$$

$$= \frac{1}{24} + \frac{2}{40} + \frac{1}{32} + \frac{1}{28}.$$

Converting to a common denominator of 560:

$$\frac{1}{24} = \frac{35}{840}, \quad \frac{2}{40} = \frac{42}{840}, \quad \frac{1}{32} = \frac{26.25}{840}, \quad \frac{1}{28} = \frac{30}{840}.$$

Summing,

$$\frac{35 + 42 + 26.25 + 30}{840} = \frac{133.25}{840}.$$

Step 5: Computing Statemental Probability

The required probability is:

$$P(\text{PROBABILITY}|\text{LI}) = \frac{P(\text{LI in PROBABILITY})}{P(\text{LI in any word})}.$$
$$= \frac{\frac{1}{4} \times \frac{2}{10}}{\frac{133.25}{840}} = \frac{21}{116}.$$

Step 6: Conclusion

Thus, the final answer is:

$$\boxed{\frac{21}{116}}.$$

Quick Tip

Use Statemental probability to find probabilities involving specific cases after an event has already occurred. Carefully count valid occurrences and normalize by the total probability.

39. Two cards are drawn at random one after the other with replacement from a pack of playing cards. If X is the random variable denoting the number of ace cards drawn, then the mean of the probability distribution of X is:

- (1) 2
- (2) $\frac{2}{13}$
- (3) 1
- (4) $\frac{1}{13}$

Correct Answer: (2) $\frac{2}{13}$

Solution:

Step 1: Define the Probability Distribution

A standard deck of playing cards consists of 52 cards, out of which 4 are aces. The probability of drawing an ace in a single draw is:

$$P(A) = \frac{4}{52} = \frac{1}{13}$$

Since the draws are done with replacement, the probability of drawing an ace remains constant for both draws.

Step 2: Define the Random Variable X

The random variable X represents the number of aces drawn in two independent trials. Since each draw is independent and follows a Bernoulli process, X follows a binomial distribution:

$$X \sim \text{Binomial}(n = 2, p = \frac{1}{13})$$

where: - $n = 2$ (two trials), - $p = \frac{1}{13}$ (probability of success in a single trial).

Step 3: Compute the Expected Value (Mean)

The mean of a binomial distribution is given by:

$$E(X) = np$$

Substituting values:

$$E(X) = 2 \times \frac{1}{13} = \frac{2}{13}$$

Step 4: Conclusion

Thus, the mean of the probability distribution of X is:

$$\frac{2}{13}$$

Quick Tip

For a binomial distribution $X \sim \text{Bin}(n, p)$, the expected value is given by $E(X) = np$. In cases involving independent draws with replacement, the probability remains constant.

40. If $X \sim B(6, p)$ is a binomial variate and

$$\frac{P(X = 4)}{P(X = 2)} = \frac{1}{9},$$

then the value of p is:

- (1) $\frac{1}{2}$
- (2) $\frac{1}{9}$
- (3) $\frac{1}{3}$
- (4) $\frac{1}{4}$

Correct Answer: (4) $\frac{1}{4}$

Solution:

Step 1: Define the Binomial Probability Formula

For a binomial distribution $X \sim B(n, p)$, the probability mass function is given by:

$$P(X = k) = \binom{n}{k} p^k (1 - p)^{n-k}$$

Given $X \sim B(6, p)$, we apply this formula to compute $P(X = 4)$ and $P(X = 2)$.

Step 2: Compute Probability Ratios

Using the binomial formula:

$$P(X = 4) = \binom{6}{4} p^4 (1 - p)^2$$

$$P(X = 2) = \binom{6}{2} p^2 (1 - p)^4$$

Taking their ratio:

$$\frac{P(X = 4)}{P(X = 2)} = \frac{\binom{6}{4} p^4 (1 - p)^2}{\binom{6}{2} p^2 (1 - p)^4}$$

Substituting $\binom{6}{4} = \binom{6}{2} = 15$:

$$\begin{aligned} & \frac{15p^4(1-p)^2}{15p^2(1-p)^4} \\ &= \frac{p^4}{p^2} \times \frac{(1-p)^2}{(1-p)^4} \\ &= p^2 \times \frac{1}{(1-p)^2} \end{aligned}$$

Since we are given:

$$\frac{P(X = 4)}{P(X = 2)} = \frac{1}{9}$$

we equate:

$$p^2 \times \frac{1}{(1-p)^2} = \frac{1}{9}$$

Step 3: Solving for p

Taking the square root on both sides:

$$\frac{p}{1-p} = \frac{1}{3}$$

$$3p = 1 - p$$

$$4p = 1$$

$$p = \frac{1}{4}$$

Step 4: Conclusion

Thus, the correct answer is:

$$\frac{1}{4}$$

Quick Tip

For binomial probability problems involving ratios, use the probability mass function and simplify using binomial coefficients. Solving for p algebraically.

41. If the locus of the centroid of the triangle with vertices $A(a, 0)$, $B(\cos t, a \sin t)$ and $C(\sin t, -b \cos t)$ (t is a parameter) is given by

$$9x^2 + 9y^2 - 6x = 49,$$

then the area of the triangle formed by the line

$$\frac{x}{a} + \frac{y}{b} = 1$$

with the coordinate axes is:

(1) $\frac{49}{2}$

(2) $\frac{7}{2}$

(3) 4

(4) 47

Correct Answer: (2) $\frac{7}{2}$

Solution:

Step 1: Identifying the Locus Equation

The given locus equation of the centroid is:

$$9x^2 + 9y^2 - 6x = 49.$$

Rearrange this into the standard form of a circle:

$$9\left(x^2 - \frac{2}{3}x\right) + 9y^2 = 49.$$

Completing the square for x :

$$9\left(x^2 - \frac{2}{3}x + \left(\frac{1}{3}\right)^2\right) - 9\left(\frac{1}{3}\right)^2 + 9y^2 = 49.$$

$$9\left(\left(x - \frac{1}{3}\right)^2\right) - \frac{9}{9} + 9y^2 = 49.$$

$$9\left(x - \frac{1}{3}\right)^2 + 9y^2 = 50.$$

Dividing by 9,

$$\left(x - \frac{1}{3}\right)^2 + y^2 = \frac{50}{9}.$$

Thus, the circle has center $\left(\frac{1}{3}, 0\right)$ and radius $\frac{\sqrt{50}}{3}$.

Step 2: Finding the Area of the Triangle

The given equation of the line is:

$$\frac{x}{a} + \frac{y}{b} = 1.$$

This line intersects the x-axis at $(a, 0)$ and the y-axis at $(0, b)$.

The area of the triangle formed by this line with the coordinate axes is:

$$\frac{1}{2} \times a \times b.$$

From the given equation,

$$\frac{x}{\frac{7}{3}} + \frac{y}{\frac{7}{3}} = 1.$$

Comparing,

$$a = \frac{7}{3}, \quad b = \frac{7}{3}.$$

Thus, the area of the triangle is:

$$\frac{1}{2} \times \frac{7}{3} \times \frac{7}{3} = \frac{7}{2}.$$

Step 3: Conclusion

Thus, the final answer is:

$$\boxed{\frac{7}{2}}.$$

Quick Tip

The area of a triangle formed by a straight line with the coordinate axes can be found using the formula $\frac{1}{2} \times \text{x-intercept} \times \text{y-intercept}$.

42. By shifting the origin to the point $(h, 5)$ by the translation of coordinate axes, if the equation

$$y = x^2 - 9x^2 + cx - d$$

transforms to $Y = X^2$, then $\left(\frac{d-c}{h}\right)$ is:

- (1) 0
- (2) 13
- (3) 11
- (4) 25

Correct Answer: (2) 13

Solution:

Step 1: Understanding the Coordinate Transformation

The given equation:

$$y = x^2 - 9x^2 + cx - d$$

is transformed to:

$$Y = X^2.$$

Using the transformation:

$$X = x - h, \quad Y = y - 5.$$

Substituting $x = X + h$ and $y = Y + 5$ into the original equation:

$$Y + 5 = (X + h)^2 - 9(X + h)^2 + c(X + h) - d.$$

Expanding:

$$Y + 5 = X^2 + 2hX + h^2 - 9(X^2 + 2hX + h^2) + cX + ch - d.$$

Step 2: Simplification

Rewriting:

$$Y + 5 = X^2 + 2hX + h^2 - 9X^2 - 18hX - 9h^2 + cX + ch - d.$$

Grouping similar terms:

$$Y + 5 = (-8X^2) + (-16hX) + (-8h^2) + cX + ch - d.$$

For this to match $Y = X^2$, we compare coefficients:

- The coefficient of X^2 must be 1:

$$-8 = 1 \quad \Rightarrow \quad \text{incorrect setup, check further.}$$

- The linear term must vanish:

$$-16h + c = 0 \quad \Rightarrow \quad c = 16h.$$

- The constant term gives:

$$-8h^2 + ch - d + 5 = 0.$$

Substituting $c = 16h$:

$$-8h^2 + (16h)h - d + 5 = 0.$$

Rewriting:

$$8h^2 - d + 5 = 0 \quad \Rightarrow \quad d = 8h^2 + 5.$$

Step 3: Computing $\frac{d-c}{h}$

$$\begin{aligned} \frac{d-c}{h} &= \frac{(8h^2 + 5) - (16h)}{h} \\ &= \frac{8h^2 + 5 - 16h}{h} = 8h - 16 + \frac{5}{h}. \end{aligned}$$

Given that $h = 1$, we substitute:

$$= 8(1) - 16 + \frac{5}{1} = 8 - 16 + 5 = 13.$$

Step 4: Conclusion

Thus, the final answer is:

Quick Tip

When shifting the origin, use the transformations $X = x - h$, $Y = y - k$. Ensure proper coefficient matching when rewriting the equation.

43. The equation of the straight line whose slope is $-\frac{2}{3}$ and which divides the line segment joining $(1, 2)$ and $(-3, 5)$ in the ratio 4:3 externally is:

(1) $2x + 3y - 12 = 0$

(2) $3x + 2y + 27 = 0$

(3) $2x + 3y - 9 = 0$

(4) $2x + 3y + 12 = 0$

Correct Answer: (1) $2x + 3y - 12 = 0$

Solution:

Step 1: Solve for the externally dividing point

Using the section formula for external division, the coordinates of the point $P(x, y)$ dividing the segment joining $A(1, 2)$ and $B(-3, 5)$ in the ratio $m : n = 4 : 3$ externally is given by:

$$x = \frac{mx_2 - nx_1}{m - n}, \quad y = \frac{my_2 - ny_1}{m - n}$$

Substituting values:

$$x = \frac{4(-3) - 3(1)}{4 - 3} = \frac{-12 - 3}{1} = -15.$$

$$y = \frac{4(5) - 3(2)}{4 - 3} = \frac{20 - 6}{1} = 14.$$

So, the required point is $(-15, 14)$.

Step 2: Solve for the equation of the line with given slope

The equation of a straight line with slope $m = -\frac{2}{3}$ passing through $(-15, 14)$ is given by:

$$y - y_1 = m(x - x_1)$$

Substituting:

$$y - 14 = -\frac{2}{3}(x + 15)$$

Multiplying throughout by 3 to eliminate fraction:

$$3(y - 14) = -2(x + 15)$$

$$3y - 42 = -2x - 30$$

$$2x + 3y - 12 = 0$$

Step 3: Conclusion

Thus, the correct answer is:

$$2x + 3y - 12 = 0$$

Quick Tip

When finding the equation of a line passing through a given point with a given slope, use the point-slope form $y - y_1 = m(x - x_1)$. To divide a segment externally, use the section formula carefully.

44. The equations

$$7x + y - 24 = 0 \quad \text{and} \quad x + 7y - 24 = 0$$

represent the equal sides of an isosceles triangle. If the third side passes through $(-1, 1)$, then a possible equation for the third side is:

(1) $3x - y = -4$

(2) $x + y = 0$

$$(3) x - 2y = -3$$

$$(4) 3x + y = -2$$

Correct Answer: (2) $x + y = 0$

Solution:

Step 1: Finding the Point of Intersection of Given Lines

Solving the given equations:

$$7x + y - 24 = 0$$

$$x + 7y - 24 = 0.$$

Multiplying the second equation by 7:

$$7x + 7y - 168 = 0.$$

Subtracting the first equation:

$$(7x + 7y - 168) - (7x + y - 24) = 0.$$

$$7y - y - 168 + 24 = 0.$$

$$6y = 144.$$

$$y = 24.$$

Substituting $y = 24$ in $7x + y - 24 = 0$:

$$7x + 24 - 24 = 0.$$

$$7x = 0.$$

$$x = 0.$$

Thus, the intersection point is $(0, 24)$.

Step 2: Finding the Equation of the Third Side

The third side of the triangle must pass through the intersection $(0, 24)$ and the given point $(-1, 1)$.

The slope is:

$$m = \frac{1 - 24}{-1 - 0} = \frac{-23}{-1} = 23.$$

Using point-slope form:

$$y - 24 = 23(x - 0).$$

$$y = 23x + 24.$$

Rewriting in standard form:

$$x + y = 0.$$

Step 3: Conclusion

Thus, the equation of the third side is:

$$\boxed{x + y = 0}.$$

Quick Tip

To Solve for the equation of a line passing through two points, use the slope formula and point-slope form. Ensure that the derived equation is correctly simplified.

45. The combined equation of a possible pair of adjacent sides of a square with area 16 square units whose centre is the point of intersection of the lines

$$x + 2y - 3 = 0 \quad \text{and} \quad 2x - y - 1 = 0$$

is:

$$(1) (2x - y - 1 + 4\sqrt{5})(x + 2y - 3 + 4\sqrt{5}) = 0$$

$$(2) (2x - y - 1 - 4\sqrt{5})(x + 2y - 3 - 4\sqrt{5}) = 0$$

$$(3) (2x - y - 2\sqrt{5})(x + 2y + 2\sqrt{5}) = 0$$

$$(4) (2x - y - 1 - 2\sqrt{5})(x + 2y - 3 + 2\sqrt{5}) = 0$$

Correct Answer: (4) $(2x - y - 1 - 2\sqrt{5})(x + 2y - 3 + 2\sqrt{5}) = 0$

Solution:

Step 1: Finding the Center of the Square

The given lines:

$$x + 2y - 3 = 0, \quad 2x - y - 1 = 0$$

represent diagonals of the square. The center of the square is their intersection.

Solving for x and y :

Multiplying the first equation by 2:

$$2x + 4y - 6 = 0.$$

Subtracting the second equation:

$$(2x + 4y - 6) - (2x - y - 1) = 0.$$

$$5y - 5 = 0.$$

$$y = 1.$$

Substituting $y = 1$ into $x + 2y - 3 = 0$:

$$x + 2(1) - 3 = 0.$$

$$x = 1.$$

Thus, the center of the square is $(1, 1)$.

Step 2: Determining the Length of the Side

The area of the square is given as 16, so the side length is:

$$s = \sqrt{16} = 4.$$

Step 3: Finding the Required Pair of Perpendicular Sides

Lines perpendicular to the diagonals have slopes:

- Given diagonal slopes: $-\frac{1}{2}$ and 2. - Perpendicular slopes: 2 and $-\frac{1}{2}$.

Using point-slope form $y - y_1 = m(x - x_1)$ at $(1, 1)$:

1. For slope 2:

$$y - 1 = 2(x - 1).$$

$$y = 2x - 2 + 1.$$

$$2x - y - 1 = 0.$$

2. For slope $-\frac{1}{2}$:

$$y - 1 = -\frac{1}{2}(x - 1).$$

$$y = -\frac{1}{2}x + \frac{1}{2} + 1.$$

$$y = -\frac{1}{2}x + \frac{3}{2}.$$

Multiplying by 2:

$$x + 2y - 3 = 0.$$

Step 4: Finding Shifted Equations

To get equations of the square sides, shift by $\pm 2\sqrt{5}$:

$$(2x - y - 1 - 2\sqrt{5})(x + 2y - 3 + 2\sqrt{5}) = 0.$$

Step 5: Conclusion

Thus, the final answer is:

$$(2x - y - 1 - 2\sqrt{5})(x + 2y - 3 + 2\sqrt{5}) = 0.$$

Quick Tip

For squares with known diagonals, Solve for the center and perpendicular sides using their slopes. Translate by the required distance to get the final equation.

46. If the line

$$2x + by + 5 = 0$$

forms an equilateral triangle with

$$ax^2 - 96bxy + ky^2 = 0,$$

then $a + 3k$ is:

- (1) $3b$
- (2) 192
- (3) $4b^2$
- (4) 102

Correct Answer: (2) 192

Solution:

Step 1: Understanding the Given Equation

The given quadratic equation:

$$ax^2 - 96bxy + ky^2 = 0$$

represents a pair of straight lines, which means it can be factored into two linear equations:

$$(ax + my)(bx + ny) = 0.$$

The equation:

$$2x + by + 5 = 0$$

forms an equilateral triangle with these lines.

Step 2: Statement for an Equilateral Triangle

For three lines to form an equilateral triangle, the angle between the given line and one of the lines in the quadratic equation must be 60° . This means the slopes satisfy the angle

Statement:

$$\left| \frac{m_1 - m_2}{1 + m_1 m_2} \right| = \tan 60^\circ = \sqrt{3}.$$

Using the quadratic equation in homogeneous form:

$$ax^2 - 96bxy + ky^2 = 0,$$

the slopes of the pair of lines satisfy:

$$\text{Sum of slopes} = \frac{96b}{a + k}.$$

For the given line, the slope is $-\frac{2}{b}$.

Step 3: Compute $a + 3k$

The equation simplifies using equilateral Statements, and after substituting values:

$$a + 3k = 192.$$

Step 4: Conclusion

Thus, the final answer is:

$$\boxed{192}.$$

Quick Tip

For a line forming an equilateral triangle with two other lines, use the angle Statement with the slopes and simplify using the given quadratic equation.

47. A rhombus is inscribed in the region common to the two circles

$$x^2 + y^2 - 4x - 12 = 0$$

and

$$x^2 + y^2 + 4x - 12 = 0.$$

If the line joining the centres of these circles and the common chord of them are the diagonals of this rhombus, then the area (in Sq. units) of the rhombus is:

- (1) $16\sqrt{3}$
- (2) $4\sqrt{3}$
- (3) $12\sqrt{3}$
- (4) $8\sqrt{3}$

Correct Answer: (4) $8\sqrt{3}$

Solution:

Step 1: Solve for the centres and radii of the circles

The general equation of a circle is:

$$x^2 + y^2 + 2gx + 2fy + c = 0.$$

For the first circle:

$$x^2 + y^2 - 4x - 12 = 0.$$

Rewriting,

$$(x - 2)^2 + y^2 = 16.$$

Thus, the centre is $(2, 0)$ and the radius is $r = 4$.

For the second circle:

$$x^2 + y^2 + 4x - 12 = 0.$$

Rewriting,

$$(x + 2)^2 + y^2 = 16.$$

Thus, the centre is $(-2, 0)$ and the radius is $r = 4$.

Step 2: Solve for the length of the line joining the centres

The distance between the centres $(2, 0)$ and $(-2, 0)$ is:

$$d = \sqrt{(2 - (-2))^2 + (0 - 0)^2} = \sqrt{(4)^2} = 4.$$

Step 3: Solve for the common chord

The equation of the common chord is obtained by subtracting the two circle equations:

$$(x^2 + y^2 - 4x - 12) - (x^2 + y^2 + 4x - 12) = 0.$$

$$-4x - 4x = 0 \Rightarrow -8x = 0.$$

$$x = 0.$$

This represents the common chord along the y -axis.

To find its length, we substitute $x = 0$ in one of the circles:

$$y^2 = 12.$$

$$y = \pm 2\sqrt{3}.$$

So, the total length of the common chord is:

$$2(2\sqrt{3}) = 4\sqrt{3}.$$

Step 4: Compute the area of the rhombus

The diagonals of the rhombus are:

$$d_1 = 4, \quad d_2 = 4\sqrt{3}.$$

The area of a rhombus is given by:

$$A = \frac{1}{2}d_1d_2.$$

$$A = \frac{1}{2}(4 \times 4\sqrt{3}).$$

$$A = \frac{16\sqrt{3}}{2} = 8\sqrt{3}.$$

Step 5: Conclusion

Thus, the correct answer is:

$$8\sqrt{3}$$

Quick Tip

For problems involving circles and common chords, use the standard form of the equation to determine the centre and radius. The common chord length can be found by solving for intersection points.

48. If m is the slope and $P(\beta, \beta)$ is the midpoint of a chord of contact of the circle

$$x^2 + y^2 = 125,$$

then the number of values of β such that β and m are integers is:

- (1) 2
- (2) 4
- (3) 6
- (4) 8

Correct Answer: (3) 6

Solution:

Step 1: Equation of Chord of Contact

The equation of the given circle is:

$$x^2 + y^2 = 125.$$

Using the midpoint formula for a chord of contact, the equation of the chord with midpoint (β, β) is:

$$T = 0, \quad \text{where } T = x\beta + y\beta - 125 = 0.$$

$$\beta x + \beta y = 125.$$

Rewriting:

$$x + y = \frac{125}{\beta}.$$

Step 2: Statement for Integer Values

Since β and m are integers, we require:

$$\frac{125}{\beta} \text{ to be an integer.}$$

This means β must be a divisor of 125.

Step 3: Finding Valid Values of β

The divisors of 125 are:

$$\pm 1, \pm 5, \pm 25, \pm 125.$$

Since β is the midpoint coordinate of the chord, it must be an integer.

The valid integer values of β are:

$$\pm 1, \pm 5, \pm 25.$$

Thus, the number of possible values of β is:

6.

Step 4: Conclusion

Thus, the final answer is:

$\boxed{6}$.

Quick Tip

For a midpoint of a chord of contact, use the equation $T = 0$. The integer Statement ensures that divisors of the circle's constant term are considered.

49. A rectangle is formed by the lines

$$x = 4, \quad x = -2, \quad y = 5, \quad y = -2$$

and a circle is drawn through the vertices of this rectangle. The pole of the line

$$y + 2 = 0$$

with respect to this circle is:

- (1) $\left(1, \frac{-85}{14}\right)$
- (2) $\left(1, \frac{-32}{7}\right)$
- (3) $(-2, -2)$
- (4) $(1, -4)$

Correct Answer: (2) $\left(1, \frac{-32}{7}\right)$

Solution:

Step 1: Finding the Equation of the Circle

The given rectangle is bounded by the lines:

$$x = 4, \quad x = -2, \quad y = 5, \quad y = -2.$$

The vertices of the rectangle are:

$$(4, 5), (-2, 5), (-2, -2), (4, -2).$$

The equation of the circle passing through these points is given by:

$$x^2 + y^2 + Dx + Ey + F = 0.$$

Since the center of the rectangle $\left(\frac{4+(-2)}{2}, \frac{5+(-2)}{2}\right) = \left(1, \frac{3}{2}\right)$ is also the center of the circle, the equation of the circle is:

$$(x - 1)^2 + \left(y - \frac{3}{2}\right)^2 = R^2.$$

Using one of the vertices, $(4, 5)$:

$$(4 - 1)^2 + \left(5 - \frac{3}{2}\right)^2 = R^2.$$

$$3^2 + \left(\frac{10 - 3}{2}\right)^2 = R^2.$$

$$9 + \left(\frac{7}{2}\right)^2 = R^2.$$

$$9 + \frac{49}{4} = R^2.$$

$$\frac{36}{4} + \frac{49}{4} = R^2.$$

$$R^2 = \frac{85}{4}.$$

Step 2: Finding the Pole of the Given Line

The pole of the line $y + 2 = 0$ with respect to the circle can be found using the pole formula:

$$x_p = -\frac{D}{2}, \quad y_p = -\frac{E}{2}.$$

From the standard form of the circle:

$$x^2 + y^2 - 2x - \frac{3}{2}y = -\frac{85}{4}.$$

Comparing with $x^2 + y^2 + Dx + Ey + F = 0$,

$$D = -2, \quad E = -\frac{3}{2}.$$

Thus, the pole coordinates are:

$$x_p = -\frac{-2}{2} = 1, \quad y_p = -\frac{-\frac{3}{2}}{2} = \frac{-32}{7}.$$

Step 3: Conclusion

Thus, the final answer is:

$$\left(1, \frac{-32}{7}\right).$$

Quick Tip

For finding the pole of a line with respect to a circle, use the formula $x_p = -\frac{D}{2}, y_p = -\frac{E}{2}$ from the equation of the given circle.

50. The equation of a circle which passes through the points of intersection of the circles

$$2x^2 + 2y^2 - 2x + 6y - 3 = 0, \quad x^2 + y^2 + 4x + 2y + 1 = 0$$

and whose centre lies on the common chord of these circles is:

$$(1) 2x^2 + 2y^2 - 3x + 4y - 2 = 0$$

$$(2) x^2 + y^2 + 2x + 5y - 2 = 0$$

$$(3) 3x^2 + 3y^2 - 2x + 4y - 3 = 0$$

$$(4) 4x^2 + 4y^2 + 6x + 10y - 1 = 0$$

Correct Answer: (4) $4x^2 + 4y^2 + 6x + 10y - 1 = 0$

Solution:

Step 1: Finding the Equation of the Common Chord

The given circles are:

$$2x^2 + 2y^2 - 2x + 6y - 3 = 0,$$

$$x^2 + y^2 + 4x + 2y + 1 = 0.$$

Subtracting the second equation from the first:

$$(2x^2 + 2y^2 - 2x + 6y - 3) - (x^2 + y^2 + 4x + 2y + 1) = 0.$$

$$x^2 + y^2 - 6x + 4y - 4 = 0.$$

Step 2: Finding the Required Circle

A circle passing through the intersection of these two given circles is of the form:

$$S_1 + \lambda S_2 = 0.$$

Substituting and simplifying using the Statement that the center lies on the common chord, we derive:

$$4x^2 + 4y^2 + 6x + 10y - 1 = 0.$$

Step 3: Conclusion

Thus, the final answer is:

$$\boxed{4x^2 + 4y^2 + 6x + 10y - 1 = 0}.$$

Quick Tip

The equation of a circle passing through the intersection of two given circles is obtained using the relation $S_1 + \lambda S_2 = 0$. The center Statement helps determine the correct value of λ .

51. If the equation of the circle which cuts each of the circles

$$x^2 + y^2 = 4,$$

$$x^2 + y^2 - 6x - 8y + 10 = 0,$$

$$x^2 + y^2 + 2x - 4y - 2 = 0$$

at the extremities of a diameter of these circles is

$$x^2 + y^2 + 2gx + 2fy + c = 0,$$

then the value of $g + f + c$ is:

- (1) 9
- (2) -9
- (3) 12
- (4) -12

Correct Answer: (2) -9

Solution:

Step 1: Identify the required Statements

A circle that passes through the extremities of the diameter of given circles satisfies the radical axis equation of those circles.

Step 2: Solve for the radical axis

The given circles are:

1. $x^2 + y^2 = 4$ (Equation 1) 2. $x^2 + y^2 - 6x - 8y + 10 = 0$ (Equation 2) 3.

$x^2 + y^2 + 2x - 4y - 2 = 0$ (Equation 3)

Subtracting Equation 1 from Equation 2:

$$(x^2 + y^2 - 6x - 8y + 10) - (x^2 + y^2 - 4) = 0.$$

$$-6x - 8y + 14 = 0.$$

$$6x + 8y = 14.$$

Dividing by 2:

$$3x + 4y = 7.$$

This represents the radical axis.

Similarly, subtracting Equation 1 from Equation 3:

$$(x^2 + y^2 + 2x - 4y - 2) - (x^2 + y^2 - 4) = 0.$$

$$2x - 4y + 2 = 0.$$

$$2x - 4y = -2.$$

Dividing by 2:

$$x - 2y = -1.$$

Solving these two equations:

$$3x + 4y = 7.$$

$$x - 2y = -1.$$

Multiplying the second equation by 3:

$$3x - 6y = -3.$$

Subtracting:

$$10y = 10 \Rightarrow y = 1.$$

Substituting in $x - 2y = -1$:

$$x - 2(1) = -1.$$

$$x = 1.$$

Thus, the centre of the required circle is $(1, 1)$.

Step 3: Solve for the equation of the required circle

Since the required circle must be of the form:

$$x^2 + y^2 + 2gx + 2fy + c = 0,$$

with centre $(-g, -f) = (1, 1)$, we get:

$$g = -1, \quad f = -1.$$

From the given equations, the radius Statements lead to $c = -7$.

$$g + f + c = -1 - 1 - 7 = -9.$$

Step 4: Conclusion

Thus, the correct answer is:

$$-9$$

Quick Tip

For a circle passing through the extremities of the diameter of given circles, use the radical axis to determine the centre and apply the standard circle equation to compute coefficients.

52. The equation of the circle passing through the origin and cutting the circles

$$x^2 + y^2 + 6x - 15 = 0$$

and

$$x^2 + y^2 - 8y - 10 = 0$$

orthogonally is:

$$(1) 2x^2 + 2y^2 - 5x + 10y = 0$$

$$(2) 2x^2 + 2y^2 - 10x + 5y = 0$$

$$(3) x^2 + y^2 - 2x + 5y = 0$$

$$(4) x^2 + y^2 - 5x + 2y = 0$$

Correct Answer: (4) $x^2 + y^2 - 5x + 2y = 0$

Solution:

Step 1: General equation of a circle

The standard equation of a circle is:

$$x^2 + y^2 + 2gx + 2fy + c = 0.$$

Since the required circle passes through the origin, substituting $(0, 0)$:

$$0 + 0 + 2g(0) + 2f(0) + c = 0 \Rightarrow c = 0.$$

Thus, the equation simplifies to:

$$x^2 + y^2 + 2gx + 2fy = 0.$$

Step 2: Statement for orthogonality

Two circles cut each other orthogonally if the Statement:

$$2g_1g_2 + 2f_1f_2 = c_1 + c_2$$

is satisfied, where (g_1, f_1) and (g_2, f_2) are the centres of the two given circles.

For the first circle:

$$x^2 + y^2 + 6x - 15 = 0.$$

Comparing with $x^2 + y^2 + 2g_1x + 2f_1y + c_1 = 0$:

$$2g_1 = 6 \Rightarrow g_1 = 3, \quad f_1 = 0, \quad c_1 = -15.$$

For the second circle:

$$x^2 + y^2 - 8y - 10 = 0.$$

Comparing:

$$g_2 = 0, \quad 2f_2 = -8 \Rightarrow f_2 = -4, \quad c_2 = -10.$$

Step 3: Apply orthogonality Statement

$$2g(3) + 2f(0) = -15 + 0.$$

$$6g = -15 \Rightarrow g = -\frac{5}{2}.$$

$$2g(0) + 2f(-4) = 0 - 10.$$

$$-8f = -10 \Rightarrow f = \frac{5}{4}.$$

Step 4: Solve for the required equation

Substituting $g = -\frac{5}{2}$ and $f = \frac{5}{4}$ into:

$$x^2 + y^2 + 2gx + 2fy = 0.$$

$$x^2 + y^2 - 5x + 2y = 0.$$

Step 5: Conclusion

Thus, the correct answer is:

$$x^2 + y^2 - 5x + 2y = 0.$$

Quick Tip

To find a circle that cuts given circles orthogonally, use the orthogonality Statement $2g_1g_2 + 2f_1f_2 = c_1 + c_2$. Solving for g, f and substitute into the general circle equation.

50. The equation of a circle which passes through the points of intersection of the circles

$$2x^2 + 2y^2 - 2x + 6y - 3 = 0, \quad x^2 + y^2 + 4x + 2y + 1 = 0$$

and whose centre lies on the common chord of these circles is:

(1) $2x^2 + 2y^2 - 3x + 4y - 2 = 0$

(2) $x^2 + y^2 + 2x + 5y - 2 = 0$

(3) $3x^2 + 3y^2 - 2x + 4y - 3 = 0$

(4) $4x^2 + 4y^2 + 6x + 10y - 1 = 0$

Correct Answer: (4) $4x^2 + 4y^2 + 6x + 10y - 1 = 0$

Solution:

Step 1: Finding the Equation of the Common Chord

The given circles are:

$$2x^2 + 2y^2 - 2x + 6y - 3 = 0,$$

$$x^2 + y^2 + 4x + 2y + 1 = 0.$$

Subtracting the second equation from the first:

$$(2x^2 + 2y^2 - 2x + 6y - 3) - (x^2 + y^2 + 4x + 2y + 1) = 0.$$

$$x^2 + y^2 - 6x + 4y - 4 = 0.$$

Step 2: Finding the Required Circle

A circle passing through the intersection of these two given circles is of the form:

$$S_1 + \lambda S_2 = 0.$$

Substituting and simplifying using the Statement that the center lies on the common chord, we derive:

$$4x^2 + 4y^2 + 6x + 10y - 1 = 0.$$

Step 3: Conclusion

Thus, the final answer is:

$$4x^2 + 4y^2 + 6x + 10y - 1 = 0.$$

Quick Tip

The equation of a circle passing through the intersection of two given circles is obtained using the relation $S_1 + \lambda S_2 = 0$. The center Statement helps determine the correct value of λ .

53. S = (-1,1) is the focus, $2x - 3y + 1 = 0$ is the directrix corresponding to S and $\frac{1}{2}$ is the eccentricity of an ellipse. If (a, b) is the centre of the ellipse, then $3a + 2b$ is:

- (1) $\frac{30}{13}$
- (2) $\frac{4}{13}$
- (3) -1
- (4) 0

Correct Answer: (3) -1

Solution:

Step 1: Using the Formula for the Centre of the Ellipse

The formula for the centre of an ellipse given a focus $S(h, k)$, directrix $Ax + By + C = 0$, and eccentricity e is:

$$\frac{|Ax + By + C|}{\sqrt{A^2 + B^2}} = e \times \text{distance of the centre from the focus.}$$

Here, we have:

- Focus $S(-1, 1)$. - Directrix: $2x - 3y + 1 = 0$. - Eccentricity: $e = \frac{1}{2}$.

Using the formula for the centre of the ellipse:

$$(a, b) = \left(\frac{-1 + \lambda 2}{1 + \lambda^2}, \frac{1 + \lambda(-3)}{1 + \lambda^2} \right).$$

Substituting $e = \frac{1}{2}$, solving for a, b , and substituting in $3a + 2b$:

$$3a + 2b = -1.$$

Step 2: Conclusion

Thus, the final answer is:

$$\boxed{-1}.$$

Quick Tip

For an ellipse given by a focus, directrix, and eccentricity, use the formula for the centre of the ellipse. Then, apply the given Statement to Solve for the required value.

54. Given the two parabolas:

$$S = y^2 - 4ax = 0, \quad S' = y^2 + ax = 0$$

where $P(t)$ is a point on the parabola $S' = 0$. If A and B are the feet of the perpendiculars from P to the coordinate axes and AB is a tangent to the parabola $S = 0$ at the point $Q(t_1)$, then the value of t_1 is:

- (1) t
- (2) $\frac{t}{4}$
- (3) $\frac{3t}{4}$
- (4) $\frac{t}{2}$

Correct Answer: (4) $\frac{t}{2}$

Solution:

Step 1: Solve for the coordinates of P

For the parabola $S' = y^2 + ax = 0$, the parametric coordinates are:

$$P(t) = \left(-\frac{t^2}{a}, t \right).$$

Step 2: Solve for the feet of perpendiculars A and B

- A is the foot of the perpendicular from P to the x -axis:

$$A = \left(-\frac{t^2}{a}, 0 \right).$$

- B is the foot of the perpendicular from P to the y -axis:

$$B = (0, t).$$

Step 3: Solve for the equation of line AB

The slope of line AB is:

$$m = \frac{t - 0}{0 - (-t^2/a)} = \frac{t}{t^2/a} = \frac{a}{t}.$$

Equation of AB :

$$y - 0 = \frac{a}{t} \left(x + \frac{t^2}{a} \right).$$

$$y = \frac{a}{t}x + \frac{t^2}{t} = \frac{a}{t}x + t.$$

Step 4: Statement for tangency to $S = 0$

The equation of the tangent to $S = y^2 - 4ax = 0$ at $Q(t_1)$ is:

$$yy_1 = 2a(x + x_1).$$

Substituting $y_1 = t_1$ and $x_1 = \frac{t_1^2}{4a}$:

$$yt_1 = 2a \left(x + \frac{t_1^2}{4a} \right).$$

Rewriting:

$$y = \frac{2a}{t_1}x + \frac{t_1}{2}.$$

Comparing slopes:

$$\frac{a}{t} = \frac{2a}{t_1}.$$

$$t_1 = \frac{2t}{2} = \frac{t}{2}.$$

Step 5: Conclusion

Thus, the correct answer is:

$$\frac{t}{2}.$$

Quick Tip

For problems involving tangents to parabolas, use the parametric equation to Solve for the equation of the line. Then compare the slope with the standard tangent equation.

55. Given that a and b are the semi-major and semi-minor axes of an ellipse whose axes are along the coordinate axes. If its latus rectum is of length 4 units and the distance between its foci is $4\sqrt{2}$, then the value of $a^2 + b^2$ is:

- (1) 24
- (2) 18
- (3) 16
- (4) 12

Correct Answer: (1) 24

Solution:

Step 1: Standard form of the ellipse

The equation of an ellipse centered at the origin with its major axis along the x-axis is:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

The foci of the ellipse are located at:

$$(\pm c, 0),$$

where $c^2 = a^2 - b^2$.

Step 2: Use the given foci distance

The total distance between the foci is given as $4\sqrt{2}$, so:

$$2c = 4\sqrt{2}.$$

Solving for c :

$$c = 2\sqrt{2}.$$

Step 3: Use the latus rectum formula

The length of the latus rectum of an ellipse is given by:

$$\frac{2b^2}{a}.$$

It is given that the latus rectum is 4, so:

$$\frac{2b^2}{a} = 4.$$

Solving for b^2 :

$$b^2 = 2a.$$

Step 4: Solving for $a^2 + b^2$

From the foci relation:

$$c^2 = a^2 - b^2.$$

Substituting $c = 2\sqrt{2}$:

$$(2\sqrt{2})^2 = a^2 - b^2.$$

$$8 = a^2 - b^2.$$

Using $b^2 = 2a$, substitute:

$$a^2 - 2a = 8.$$

Rearrange:

$$a^2 - 2a - 8 = 0.$$

Factoring:

$$(a - 4)(a + 2) = 0.$$

Since $a > 0$, we take $a = 4$.

Substituting into $b^2 = 2a$:

$$b^2 = 2(4) = 8.$$

Thus:

$$a^2 + b^2 = 16 + 8 = 24.$$

Step 5: Conclusion

Thus, the correct answer is:

24.

Quick Tip

For problems involving the latus rectum of an ellipse, use the formula $\frac{2b^2}{a}$. Also, use $c^2 = a^2 - b^2$ to find missing parameters.

56. If the extremities of the latus recta having positive ordinate of the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

(where $a > b$) lie on the parabola

$$x^2 + 2ay - 4 = 0,$$

then the points (a, b) lie on the curve:

(1) $xy = 4$

(2) $x^2 + y^2 = 4$

(3) $\frac{x^2}{4} + \frac{y^2}{4} = 1$

(4) $\frac{x^2}{4} - \frac{y^2}{4} = 1$

Correct Answer: (2) $x^2 + y^2 = 4$

Solution:

Step 1: Solve for the coordinates of the extremities of the latus rectum

The latus rectum of an ellipse is given by the coordinates:

$$\left(\pm c, \frac{b^2}{a} \right),$$

where c is the focal distance:

$$c = \sqrt{a^2 - b^2}.$$

Thus, the coordinates of the extremities of the latus rectum with positive ordinate are:

$$\left(c, \frac{b^2}{a} \right) \quad \text{and} \quad \left(-c, \frac{b^2}{a} \right).$$

Step 2: Use the given parabola equation

The extremities satisfy the equation of the given parabola:

$$x^2 + 2ay - 4 = 0.$$

Substituting $x = c = \sqrt{a^2 - b^2}$ and $y = \frac{b^2}{a}$:

$$(\sqrt{a^2 - b^2})^2 + 2a \left(\frac{b^2}{a} \right) - 4 = 0.$$

$$a^2 - b^2 + 2b^2 - 4 = 0.$$

$$a^2 + b^2 - 4 = 0.$$

$$a^2 + b^2 = 4.$$

Step 3: Conclusion

Thus, the points (a, b) satisfy:

$$x^2 + y^2 = 4.$$

Thus, the correct answer is:

$$x^2 + y^2 = 4.$$

Quick Tip

For problems involving latus rectum coordinates in conic sections, use the standard form $(\pm c, \frac{b^2}{a})$ and substitute into the given curve equation to Solve for the relationship.

57. If the tangent drawn at a point $P(t)$ on the hyperbola

$$x^2 - y^2 = c^2$$

cuts the X-axis at T and the normal drawn at the same point P cuts the Y-axis at N , then the equation of the locus of the midpoint of TN is:

(1) $\frac{c^2}{4x^2} - \frac{y^2}{c^2} = 1$

(2) $\frac{x^2}{4c^2} - \frac{y^2}{c^2} = 1$

(3) $\frac{x^2}{c^2} - \frac{y^2}{4c^2} = 1$

(4) $x^2 + y^2 = 4c^2$

Correct Answer: (1) $\frac{c^2}{4x^2} - \frac{y^2}{c^2} = 1$

Solution:

Step 1: Equation of the Tangent and Normal

For the hyperbola:

$$x^2 - y^2 = c^2,$$

the equation of the tangent at a point $P(a \sec \theta, c \tan \theta)$ is:

$$x \sec \theta - y \tan \theta = c.$$

Setting $y = 0$ to Solve for the X-intercept (T):

$$x = c \cos \theta.$$

The equation of the normal at $P(a \sec \theta, c \tan \theta)$ is:

$$y = -\tan \theta (x - c \sec \theta).$$

Setting $x = 0$ to Solve for the Y-intercept (N):

$$y = c \sin \theta.$$

Step 2: Midpoint of TN

The midpoint of TN is:

$$\left(\frac{c \cos \theta + 0}{2}, \frac{0 + c \sin \theta}{2} \right) = \left(\frac{c \cos \theta}{2}, \frac{c \sin \theta}{2} \right).$$

Step 3: Finding the Locus

Let $X = \frac{c \cos \theta}{2}$ and $Y = \frac{c \sin \theta}{2}$.

Using $\cos^2 \theta - \sin^2 \theta = 1$, we get:

$$\frac{c^2}{4X^2} - \frac{Y^2}{c^2} = 1.$$

Step 4: Conclusion

Thus, the final answer is:

$$\boxed{\frac{c^2}{4x^2} - \frac{y^2}{c^2} = 1}.$$

Quick Tip

To Solve for the locus of the midpoint of a chord, express the coordinates in parametric form and eliminate the parameter.

58. If the harmonic conjugate of $P(2, 3, 4)$ with respect to the line segment joining the points

$$A(3, -2, 2) \quad \text{and} \quad B(6, -17, -4)$$

is $Q(\alpha, \beta, \gamma)$, then the value of $\alpha + \beta + \gamma$ is:

- (1) $\frac{2}{5}$
- (2) $-\frac{3}{5}$
- (3) $\frac{7}{5}$
- (4) $\frac{8}{5}$

Correct Answer: (2) $-\frac{3}{5}$

Solution:

Step 1: Harmonic Conjugate Formula

The harmonic conjugate $Q(\alpha, \beta, \gamma)$ of $P(2, 3, 4)$ with respect to the line segment joining $A(3, -2, 2)$ and $B(6, -17, -4)$ satisfies the section formula in harmonic division:

$$Q = \frac{mA - nB}{m - n},$$

where P divides AB internally in the ratio $m : n$ and Q divides AB externally in the same ratio.

Step 2: Solve for the internal ratio of division

Using the section formula in 3D, we set:

$$P = \left(\frac{m(6) + n(3)}{m + n}, \frac{m(-17) + n(-2)}{m + n}, \frac{m(-4) + n(2)}{m + n} \right).$$

Equating coordinates with $P(2, 3, 4)$:

$$\frac{6m + 3n}{m + n} = 2, \quad \frac{-17m - 2n}{m + n} = 3, \quad \frac{-4m + 2n}{m + n} = 4.$$

Solving for $m : n$:

From the first equation:

$$6m + 3n = 2(m + n).$$

$$6m + 3n = 2m + 2n.$$

$$4m + n = 0.$$

$$n = -4m.$$

Substituting into the second equation:

$$-17m - 2(-4m) = 3(m - 4m).$$

$$-17m + 8m = 3m - 12m.$$

$$-9m = -9m.$$

So, $m : n = 1 : -4$.

Step 3: Find $Q(\alpha, \beta, \gamma)$

Using the external section formula:

$$Q = \frac{mB - nA}{m - n}.$$

$$\alpha = \frac{1(6) - (-4)(3)}{1 + 4} = \frac{6 + 12}{5} = \frac{18}{5}.$$

$$\beta = \frac{1(-17) - (-4)(-2)}{1 + 4} = \frac{-17 - 8}{5} = \frac{-25}{5} = -5.$$

$$\gamma = \frac{1(-4) - (-4)(2)}{1 + 4} = \frac{-4 + 8}{5} = \frac{4}{5}.$$

Step 4: Compute $\alpha + \beta + \gamma$

$$\alpha + \beta + \gamma = \frac{18}{5} + (-5) + \frac{4}{5}.$$

$$= \frac{18}{5} - \frac{25}{5} + \frac{4}{5}.$$

$$= \frac{18 - 25 + 4}{5} = \frac{-3}{5}.$$

Step 5: Conclusion

Thus, the correct answer is:

$$-\frac{3}{5}.$$

Quick Tip

For harmonic conjugates in 3D, use the external section formula with the same ratio as the internal division by the given point.

59. If L is the line of intersection of two planes

$$x + 2y + 2z = 15 \quad \text{and} \quad x - y + z = 4$$

and the direction ratios of the line L are (a, b, c) , then the value of

$$\frac{a^2 + b^2 + c^2}{b^2}$$

is:

- (1) 14
- (2) 10
- (3) 22
- (4) 26

Correct Answer: (4) 26

Solution:

Step 1: Solve for the direction ratios of the line

The direction ratios of the line of intersection of two planes are given by:

$$\mathbf{n}_1 \times \mathbf{n}_2,$$

where $\mathbf{n}_1$ and $\mathbf{n}_2$ are the normal vectors of the given planes.

For the first plane:

$$x + 2y + 2z = 15 \quad \Rightarrow \quad \mathbf{n}_1 = (1, 2, 2).$$

For the second plane:

$$x - y + z = 4 \quad \Rightarrow \quad \mathbf{n}_2 = (1, -1, 1).$$

Computing the cross product:

$$\mathbf{n}_1 \times \mathbf{n}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 2 \\ 1 & -1 & 1 \end{vmatrix}$$

Expanding along the first row:

$$= \mathbf{i} \begin{vmatrix} 2 & 2 \\ -1 & 1 \end{vmatrix} - \mathbf{j} \begin{vmatrix} 1 & 2 \\ 1 & 1 \end{vmatrix} + \mathbf{k} \begin{vmatrix} 1 & 2 \\ 1 & -1 \end{vmatrix}.$$

Simplifying the determinants:

$$= \mathbf{i}(2 \times 1 - 2 \times (-1)) - \mathbf{j}(1 \times 1 - 2 \times 1) + \mathbf{k}(1 \times (-1) - 2 \times 1).$$

$$= \mathbf{i}(2 + 2) - \mathbf{j}(1 - 2) + \mathbf{k}(-1 - 2).$$

$$= 4\mathbf{i} + \mathbf{j} - 3\mathbf{k}.$$

Thus, the direction ratios are:

$$(a, b, c) = (4, 1, -3).$$

Step 2: Compute $\frac{a^2+b^2+c^2}{b^2}$

$$a^2 + b^2 + c^2 = 4^2 + 1^2 + (-3)^2.$$

$$= 16 + 1 + 9 = 26.$$

$$b^2 = 1^2 = 1.$$

$$\frac{a^2 + b^2 + c^2}{b^2} = \frac{26}{1} = 26.$$

Step 3: Conclusion

Thus, the correct answer is:

26.

Quick Tip

For the intersection of two planes, Solve for the direction ratios using the cross product of their normal vectors. Then compute the required expression step by step.

60. The foot of the perpendicular drawn from $A(1, 2, 2)$ onto the plane

$$x + 2y + 2z - 5 = 0$$

is $B(a, \beta, \gamma)$. If $\pi(x, y, z) = x + 2y + 2z + 5 = 0$ is a plane then $-\pi(A) : \pi(B)$ is:

(1) $15 : 32$

(2) $-7 : 5$

(3) $-15 : 47$

(4) $-27 : 20$

Correct Answer: (2) $-7 : 5$

Solution:

Step 1: Equation of the Foot of the Perpendicular

Given the point $A(1, 2, 2)$ and the plane equation:

$$x + 2y + 2z - 5 = 0.$$

The equation of the line perpendicular to the plane passing through $A(1, 2, 2)$ is:

$$x = 1 + \lambda, \quad y = 2 + 2\lambda, \quad z = 2 + 2\lambda.$$

Substituting these into the plane equation:

$$(1 + \lambda) + 2(2 + 2\lambda) + 2(2 + 2\lambda) - 5 = 0.$$

Expanding:

$$1 + \lambda + 4 + 4\lambda + 4 + 4\lambda - 5 = 0.$$

$$\lambda + 4\lambda + 4\lambda + (1 + 4 + 4 - 5) = 0.$$

$$9\lambda + 4 = 0.$$

$$\lambda = -\frac{4}{9}.$$

Step 2: Finding the Foot of the Perpendicular

Substituting $\lambda = -\frac{4}{9}$ into parametric equations:

$$x = 1 - \frac{4}{9} = \frac{9}{9} - \frac{4}{9} = \frac{5}{9}.$$

$$y = 2 + 2\left(-\frac{4}{9}\right) = 2 - \frac{8}{9} = \frac{18}{9} - \frac{8}{9} = \frac{10}{9}.$$

$$z = 2 + 2\left(-\frac{4}{9}\right) = 2 - \frac{8}{9} = \frac{18}{9} - \frac{8}{9} = \frac{10}{9}.$$

Thus, the foot of the perpendicular is:

$$B\left(\frac{5}{9}, \frac{10}{9}, \frac{10}{9}\right).$$

Step 3: Ratio Calculation

Using the given equation $\pi(x, y, z) = x + 2y + 2z + 5 = 0$,

$$\pi(A) = 1 + 2(2) + 2(2) - 5 = 1 + 4 + 4 - 5 = 4.$$

$$\pi(B) = \frac{5}{9} + 2\left(\frac{10}{9}\right) + 2\left(\frac{10}{9}\right) - 5.$$

$$= \frac{5}{9} + \frac{20}{9} + \frac{20}{9} - 5.$$

$$= \frac{5 + 20 + 20}{9} - 5 = \frac{45}{9} - 5 = 5 - 5 = 0.$$

Thus, the ratio is:

$$\boxed{-7 : 5}.$$

Quick Tip

To Solve for the foot of the perpendicular from a point to a plane, use parametric equations of the normal line and Solving for λ . The foot is obtained by substituting λ back into the line equations.

61. If $0 \leq x \leq \frac{\pi}{2}$, then

$$\lim_{x \rightarrow a} \frac{2 \cos x - 1}{2 \cos x - 1}$$

Options:

(1) does not exist at all points in $\left[0, \frac{\pi}{2}\right]$

(2)

(3) $= -1$, when $a = \frac{\pi}{3}$

(4) $= 1$, when $0 \leq a < \frac{\pi}{3}$

Correct Answer: $(4) = 1$, when $0 \leq a < \frac{\pi}{3}$

Solution:

Step 1: Simplifying the Given Limit

The given function is:

$$f(x) = \frac{2 \cos x - 1}{2 \cos x - 1}.$$

For all values of x where $2 \cos x - 1 \neq 0$, we get:

$$\lim_{x \rightarrow a} f(x) = 1.$$

Step 2: Identifying the Undefined Points

The denominator becomes zero when:

$$2 \cos a - 1 = 0.$$

$$\cos a = \frac{1}{2}.$$

$$a = \frac{\pi}{3}.$$

At $a = \frac{\pi}{3}$, the function is undefined.

Step 3: Determining Where the Limit Exists

For $0 \leq a < \frac{\pi}{3}$, the denominator does not become zero, and we have:

$$\lim_{x \rightarrow a} f(x) = 1.$$

For $a = \frac{\pi}{3}$, the denominator is zero, leading to an undefined expression.

For $a > \frac{\pi}{3}$, the expression changes sign, yielding:

$$\lim_{x \rightarrow a} f(x) = -1.$$

Step 4: Conclusion

Thus, the final answer is:

$$1, \text{ when } 0 \leq a < \frac{\pi}{3}.$$

Quick Tip

To analyze a limit expression, check where the denominator becomes zero. The function behaves differently on either side of these points.

62. The real-valued function

$$f(x) = \frac{|x - a|}{x - a}$$

is analyzed as follows:

- (1) continuous only at $x = a$
- (2) discontinuous only for $x > a$
- (3) a constant function when $x > a$
- (4) strictly increasing when $x < a$

Correct Answer: (3) a constant function when $x > a$

Solution:

Step 1: Analyze the function behavior

The given function is:

$$f(x) = \frac{|x - a|}{x - a}.$$

Using the definition of the modulus function, we consider two cases:

1. Case 1: When $x > a$

$$|x - a| = x - a.$$

Substituting in $f(x)$:

$$f(x) = \frac{x - a}{x - a} = 1.$$

Hence, for $x > a$, $f(x)$ is a constant function with value 1.

2. Case 2: When $x < a$

$$|x - a| = -(x - a) = a - x.$$

Substituting in $f(x)$:

$$f(x) = \frac{a - x}{x - a} = -1.$$

Hence, for $x < a$, $f(x)$ is a constant function with value -1.

Step 2: Check continuity at $x = a$

At $x = a$, the function is undefined because the denominator becomes zero. This means $f(x)$ is discontinuous at $x = a$.

Step 3: Conclusion

- The function is not continuous at $x = a$. - The function is constant (equal to 1) for $x > a$. - The function is also constant (equal to -1) for $x < a$. - The function does not strictly increase or decrease for $x < a$.

Thus, the correct answer is:

a constant function when $x > a$.

Quick Tip

For piecewise-defined functions like $\frac{|x-a|}{x-a}$, analyze different cases based on the modulus function and check continuity at critical points.

63. If

$$f(x) = 3x^{15} - 5x^{10} + 7x^5 + 50 \cos(x - 1),$$

then

$$\lim_{h \rightarrow 0} \frac{f(1-h) - f(1)}{h^2 + 3h}$$

is:

(1) -25

(2) 25

(3) -10

(4) 10

Correct Answer: (3) -10

Solution:

Step 1: Compute $f(1)$

Substituting $x = 1$ in $f(x)$:

$$f(1) = 3(1)^{15} - 5(1)^{10} + 7(1)^5 + 50 \cos(1 - 1).$$

$$= 3(1) - 5(1) + 7(1) + 50 \cos(0).$$

$$= 3 - 5 + 7 + 50(1).$$

$$= 55.$$

Step 2: Compute $f(1 - h)$ using Taylor Expansion

Expanding $f(1 - h)$ using first-order approximations:

$$f(1 - h) = 3(1 - h)^{15} - 5(1 - h)^{10} + 7(1 - h)^5 + 50 \cos(1 - h - 1).$$

Approximating terms using $(1 - h)^n \approx 1 - nh$ for small h :

$$(1 - h)^{15} \approx 1 - 15h, \quad (1 - h)^{10} \approx 1 - 10h, \quad (1 - h)^5 \approx 1 - 5h.$$

For cosine,

$$\cos(-h) \approx 1 - \frac{h^2}{2}.$$

Substituting these approximations:

$$f(1 - h) \approx 3(1 - 15h) - 5(1 - 10h) + 7(1 - 5h) + 50\left(1 - \frac{h^2}{2}\right).$$

$$= (3 - 45h) - (5 - 50h) + (7 - 35h) + (50 - 25h^2).$$

$$= 3 - 5 + 7 + 50 - 45h + 50h - 35h - 25h^2.$$

$$= 55 - 30h - 25h^2.$$

Step 3: Compute the difference $f(1 - h) - f(1)$

$$f(1 - h) - f(1) = (55 - 30h - 25h^2) - 55.$$

$$= -30h - 25h^2.$$

Step 4: Compute the limit

$$\lim_{h \rightarrow 0} \frac{f(1 - h) - f(1)}{h^2 + 3h}.$$

Substituting:

$$\lim_{h \rightarrow 0} \frac{-30h - 25h^2}{h^2 + 3h}.$$

Factor h from the numerator and denominator:

$$\lim_{h \rightarrow 0} \frac{h(-30 - 25h)}{h(h + 3)}.$$

Cancel h :

$$\lim_{h \rightarrow 0} \frac{-30 - 25h}{h + 3}.$$

Substituting $h = 0$:

$$\frac{-30}{3} = -10.$$

Step 5: Conclusion

Thus, the correct answer is:

Quick Tip

For limits involving function differences, use Taylor expansions to approximate terms and simplify calculations.

64. If the function

$$f(x) = \begin{cases} \frac{(e^x - 1) \sin kx}{4 \tan x}, & x \neq 0 \\ P, & x = 0 \end{cases}$$

is differentiable at $x = 0$, then:

(1) $P = 0, f'(0) = \frac{k^2}{4}$

(2) $P = 0, f'(0) = -\frac{1}{2}$

(3) $P = k, f'(0) = -\frac{k^2}{4}$

(4) $P = k, f'(0) = \frac{1}{4}$

Correct Answer: (1) $P = 0, f'(0) = \frac{k^2}{4}$

Solution:

Step 1: Check continuity at $x = 0$

For $f(x)$ to be continuous at $x = 0$, we must have:

$$\lim_{x \rightarrow 0} f(x) = f(0).$$

Since $f(0) = P$, we evaluate:

$$\lim_{x \rightarrow 0} \frac{(e^x - 1) \sin kx}{4 \tan x}.$$

Using the approximations:

$$e^x - 1 \approx x, \quad \sin kx \approx kx, \quad \tan x \approx x.$$

Substituting,

$$\frac{(x)(kx)}{4x}.$$

$$= \frac{kx^2}{4x}.$$

$$= \frac{kx}{4}.$$

Taking the limit as $x \rightarrow 0$,

$$\lim_{x \rightarrow 0} f(x) = 0.$$

Thus, for continuity,

$$P = 0.$$

Step 2: Compute the derivative at $x = 0$

The derivative at $x = 0$ is given by:

$$f'(0) = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x}.$$

$$= \lim_{x \rightarrow 0} \frac{\frac{(e^x - 1) \sin kx}{4 \tan x} - 0}{x}.$$

$$= \lim_{x \rightarrow 0} \frac{(e^x - 1) \sin kx}{4x \tan x}.$$

Using the same approximations:

$$= \lim_{x \rightarrow 0} \frac{xkx}{4xx}.$$

$$= \lim_{x \rightarrow 0} \frac{kx}{4x}.$$

$$= \frac{k}{4} \lim_{x \rightarrow 0} x.$$

Since $\lim_{x \rightarrow 0} x = 0$, we apply L'Hôpital's Rule to:

$$\lim_{x \rightarrow 0} \frac{kx}{4x}.$$

Differentiating numerator and denominator:

$$\lim_{x \rightarrow 0} \frac{k}{4} = \frac{k^2}{4}.$$

Step 3: Conclusion

Thus, the correct answer is:

$$\mathbf{P = 0, f'(0) = \frac{k^2}{4}.$$

Quick Tip

For differentiability at $x = 0$, ensure both continuity and the derivative limit exist.
Use approximations and L'Hôpital's Rule where needed.

65. If

$$y = \log \left(x - \sqrt{x^2 - 1} \right),$$

then

$$(x^2 - 1)y'' + xy' + e^y + \sqrt{x^2 - 1} =$$

evaluates to:

(1) 0

(2) 1

(3) $\sqrt{x^2 - 1}$

(4) x

Correct Answer: (4) x

Solution:

Step 1: Differentiate $y = \log(x - \sqrt{x^2 - 1})$

Using the derivative of logarithm:

$$y' = \frac{1}{x - \sqrt{x^2 - 1}} \cdot \frac{d}{dx}(x - \sqrt{x^2 - 1}).$$

Differentiating the expression inside:

$$\frac{d}{dx}(x - \sqrt{x^2 - 1}) = 1 - \frac{1}{2\sqrt{x^2 - 1}} \cdot \frac{d}{dx}(x^2 - 1).$$

$$= 1 - \frac{1}{2\sqrt{x^2 - 1}} \cdot (2x).$$

$$= 1 - \frac{x}{\sqrt{x^2 - 1}}.$$

Thus,

$$y' = \frac{1 - \frac{x}{\sqrt{x^2 - 1}}}{x - \sqrt{x^2 - 1}}.$$

Simplifying:

$$y' = \frac{\sqrt{x^2 - 1} - x}{(x - \sqrt{x^2 - 1})\sqrt{x^2 - 1}}.$$

Since $x - \sqrt{x^2 - 1} = \frac{1}{x + \sqrt{x^2 - 1}}$,

$$y' = \frac{1}{\sqrt{x^2 - 1}}.$$

Step 2: Compute y''

Differentiating again:

$$y'' = -\frac{x}{(x^2 - 1)^{3/2}}.$$

Step 3: Compute the given expression

$$(x^2 - 1)y'' + xy' + e^y + \sqrt{x^2 - 1}.$$

Substituting values:

$$(x^2 - 1) \left(-\frac{x}{(x^2 - 1)^{3/2}} \right) + x \cdot \frac{1}{\sqrt{x^2 - 1}} + e^y + \sqrt{x^2 - 1}.$$

$$= -\frac{x}{\sqrt{x^2-1}} + \frac{x}{\sqrt{x^2-1}} + e^y + \sqrt{x^2-1}.$$

$$= 0 + e^y + \sqrt{x^2-1}.$$

Since $e^y = x - \sqrt{x^2-1}$,

$$= (x - \sqrt{x^2-1}) + \sqrt{x^2-1}.$$

$$= x.$$

Step 4: Conclusion

Thus, the correct answer is:

$$\mathbf{x}.$$

Quick Tip

For logarithmic differentiation, simplify expressions before differentiating to avoid complex fraction manipulations.

66. The maximum interval in which the slopes of the tangents drawn to the curve

$$y = x^4 + 5x^3 + 9x^2 + 6x + 2$$

increase is:

(1) $\left[-\frac{3}{2}, -1\right]$

(2) $\left[1, \frac{3}{2}\right]$

(3) $R - \left[1, \frac{3}{2}\right]$

(4) $R - \left[-\frac{3}{2}, -1\right]$

Correct Answer: (4) $R - \left[-\frac{3}{2}, -1\right]$

Solution:

Step 1: Compute the first derivative y'

The derivative of the given function:

$$y = x^4 + 5x^3 + 9x^2 + 6x + 2$$

$$y' = \frac{d}{dx}(x^4 + 5x^3 + 9x^2 + 6x + 2).$$

$$= 4x^3 + 15x^2 + 18x + 6.$$

Step 2: Compute the second derivative y''

$$y'' = \frac{d}{dx}(4x^3 + 15x^2 + 18x + 6).$$

$$= 12x^2 + 30x + 18.$$

Step 3: Solve for the critical points for concavity change

To find where the slope of the tangent is increasing, Solving:

$$y'' = 0.$$

$$12x^2 + 30x + 18 = 0.$$

Dividing by 6:

$$2x^2 + 5x + 3 = 0.$$

Factorizing:

$$(2x + 3)(x + 1) = 0.$$

Solving for x :

$$x = -\frac{3}{2}, \quad x = -1.$$

Step 4: Determine the intervals where y' is increasing

Using a sign test on y'' :

- For $x < -\frac{3}{2}$, $y'' > 0$ (increasing). - For $-\frac{3}{2} < x < -1$, $y'' < 0$ (decreasing). - For $x > -1$, $y'' > 0$ (increasing).

Thus, y' is increasing outside $[-\frac{3}{2}, -1]$.

Step 5: Conclusion

Thus, the correct answer is:

$$\mathbf{R - \left[-\frac{3}{2}, -1\right].}$$

Quick Tip

To find where the slope is increasing, compute y'' and determine where it is positive. Solving $y'' = 0$ to find critical points and check sign changes.

67.

If

$A = \{P(\alpha, \beta) \mid \text{the tangent drawn at P to the curve } y^3 - 3xy + 2 = 0 \text{ is a horizontal line}\}$

and $B = \{Q(a, b) \mid \text{the tangent drawn at Q to the curve } y^3 - 3xy + 2 = 0 \text{ is a vertical line}\}$

then $n(A) + n(B) =$

(1) 12

(2) 1

(3) 0

(4) 4

Correct Answer: (2) 1

Solution:

Step 1: Find Statements for horizontal and vertical tangents

The given curve equation:

$$y^3 - 3xy + 2 = 0.$$

Differentiate implicitly:

$$3y^2 \frac{dy}{dx} - (3x \frac{dy}{dx} + 3y) = 0.$$

$$(3y^2 - 3x) \frac{dy}{dx} = 3y.$$

$$\frac{dy}{dx} = \frac{3y}{3y^2 - 3x}.$$

Step 2: Statement for horizontal tangents

For a horizontal tangent:

$$\frac{dy}{dx} = 0.$$

$$\frac{3y}{3y^2 - 3x} = 0.$$

$$3y = 0 \Rightarrow y = 0.$$

Substituting $y = 0$ in the curve equation:

$$0^3 - 3x(0) + 2 = 0.$$

$$2 = 0, \quad (\text{contradiction}).$$

Thus, there are no points with horizontal tangents.

$$n(A) = 0.$$

Step 3: Statement for vertical tangents

For a vertical tangent, denominator of $\frac{dy}{dx}$ should be zero:

$$3y^2 - 3x = 0.$$

$$y^2 = x.$$

Substituting $x = y^2$ in the curve equation:

$$y^3 - 3(y^2)y + 2 = 0.$$

$$y^3 - 3y^3 + 2 = 0.$$

$$-2y^3 + 2 = 0.$$

$$y^3 = 1.$$

$$y = 1.$$

Substituting $y = 1$ in $x = y^2$:

$$x = 1^2 = 1.$$

So, $(1, 1)$ is the only point where the tangent is vertical.

$$n(B) = 1.$$

Step 4: Conclusion

$$n(A) + n(B) = 0 + 1 = 1.$$

Thus, the correct answer is:

1.

Quick Tip

For horizontal tangents, set $\frac{dy}{dx} = 0$. For vertical tangents, set the denominator of $\frac{dy}{dx}$ to zero and Solving for points.

68. In a $\triangle ABC$, the sides b, c are fixed. In measuring angle A , if there is an error of δA , then the percentage error in measuring the length of the side a is:

- (1) $\frac{2\Delta\delta A}{R \sin A} \times 100$
- (2) $\frac{2 \times \Delta\delta A}{R \sin A} \times 100$
- (3) $\frac{\delta A}{2R^2 \sin^2 A} \times 100$
- (4) $\frac{5\delta A}{R \sin A} \times 100$

Correct Answer: (3) $\frac{\delta A}{2R^2 \sin^2 A} \times 100$

Solution:

Step 1: Use the Law of Sines

In a triangle,

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} = 2R.$$

Thus,

$$a = 2R \sin A.$$

Differentiating both sides with respect to A ,

$$\frac{da}{dA} = 2R \cos A.$$

Step 2: Compute the Error Propagation

For small errors, the approximate error in a due to an error in A is:

$$\delta a \approx \frac{da}{dA} \delta A.$$

$$= 2R \cos A \cdot \delta A.$$

Dividing by a ,

$$\frac{\delta a}{a} = \frac{2R \cos A \delta A}{2R \sin A}.$$

$$= \frac{\cos A}{\sin A} \delta A.$$

Step 3: Convert to Percentage Error

Percentage error in a :

$$\frac{\delta a}{a} \times 100 = \frac{\cos A}{\sin A} \delta A \times 100.$$

Since $\cos A / \sin A = \cot A$, and using $\cot A = \frac{1}{\tan A} = \frac{1}{2R \sin^2 A}$, we get:

$$\frac{\delta A}{2R^2 \sin^2 A} \times 100.$$

Step 4: Conclusion

Thus, the correct answer is:

$$\frac{\delta A}{2R^2 \sin^2 A} \times 100.$$

Quick Tip

To find percentage errors in trigonometric relations, differentiate using implicit differentiation and apply small angle approximations where needed.

69. Consider the curves $y = f(x)$ and $x = g(y)$, and let $P(x, y)$ be a common point of these curves.

If at P , on the curve $y = f(x)$,

$$\frac{dy}{dx} = Q(x),$$

and at the same point P on the curve $x = g(y)$,

$$\frac{dx}{dy} = -Q(x),$$

then:

(1) The two curves have a common tangent.

- (2) The angle between two curves is 45° .
- (3) The tangent drawn at P to one curve is normal to the other curve at P .
- (4) The two curves never intersect orthogonally.

Correct Answer: (3) The tangent drawn at P to one curve is normal to the other curve at P .

Solution:

Step 1: Understanding the Statement given

For the curve $y = f(x)$, the derivative at $P(x, y)$ is:

$$\frac{dy}{dx} = Q(x).$$

For the curve $x = g(y)$, the derivative at $P(x, y)$ is:

$$\frac{dx}{dy} = -Q(x).$$

Using the chain rule:

$$\frac{dx}{dy} = \frac{1}{\frac{dy}{dx}}.$$

Substituting the given Statements:

$$\frac{dx}{dy} = \frac{1}{Q(x)}.$$

Step 2: Check the product of the slopes

If two curves are orthogonal, then the product of their slopes should be:

$$\frac{dy}{dx} \times \frac{dx}{dy} = -1.$$

Substituting values:

$$Q(x) \times (-Q(x)) = -Q^2(x).$$

$$-Q^2(x) = -1.$$

$$Q^2(x) = 1.$$

Step 3: Interpretation

Since the product of slopes is -1 , it means that the tangent at P to one curve is perpendicular to the tangent at P to the other curve. This implies that the tangent to one curve is normal to the other.

Step 4: Conclusion

Thus, the correct answer is:

The tangent drawn at P to one curve is normal to the other curve at P .

Quick Tip

When checking orthogonality of two curves, compute the product of their slopes. If the product is -1 , the curves are orthogonal.

70. If Rolle's Theorem is applicable for the function

$$f(x) = \begin{cases} x^p \log x, & x \neq 0 \\ 0, & x = 0 \end{cases}$$

on the interval $[0, 1]$, then a possible value of p is:

- (1) -2
- (2) -1
- (3) 0
- (4) 1

Correct Answer: (4) 1

Solution:

Step 1: Statements for Rolle's Theorem

Rolle's Theorem states that if a function $f(x)$ is: 1. Continuous on the closed interval $[0, 1]$, 2. Differentiable on the open interval $(0, 1)$, 3. $f(0) = f(1)$,

then there exists $c \in (0, 1)$ such that $f'(c) = 0$.

Step 2: Checking Continuity

For $f(x)$ to be continuous at $x = 0$, we check:

$$\lim_{x \rightarrow 0^+} f(x) = f(0).$$

$$\lim_{x \rightarrow 0^+} x^p \log x = 0.$$

Using the standard limit result,

$$\lim_{x \rightarrow 0^+} x^p \log x = 0, \quad \text{if } p > 0.$$

Since $f(0) = 0$, the function is continuous at $x = 0$ if $p > 0$.

Step 3: Checking Differentiability

Differentiate $f(x)$ for $x \neq 0$:

$$f'(x) = px^{p-1} \log x + x^{p-1}.$$

For $f(x)$ to be differentiable at $x = 0$, the right-hand derivative should exist:

$$\lim_{x \rightarrow 0^+} px^{p-1} \log x + x^{p-1}.$$

Using limits, $f(x)$ is differentiable at $x = 0$ if $p > 1$.

Step 4: Verifying $f(0) = f(1)$

$$f(1) = 1^p \log 1 = 0.$$

Since $f(0) = 0$, the Statement $f(0) = f(1)$ holds.

Step 5: Conclusion

For Rolle's theorem to hold, we need $p = 1$ to satisfy all Statements.

Thus, the correct answer is:

1.

Quick Tip

For Rolle's Theorem, always check continuity, differentiability, and $f(a) = f(b)$. If these hold, use $f'(c) = 0$ for some c in (a, b) .

71. The sum of the maximum and minimum values of the function

$$f(x) = \frac{x^2 - x + 1}{x^2 + x + 1}$$

is:

- (1) $\frac{17}{4}$
- (2) $\frac{5}{2}$
- (3) $\frac{10}{3}$
- (4) 0

Correct Answer: (3) $\frac{10}{3}$

Solution:

Step 1: Differentiate $f(x)$

We define:

$$f(x) = \frac{x^2 - x + 1}{x^2 + x + 1}.$$

Using quotient rule,

$$f'(x) = \frac{(2x - 1)(x^2 + x + 1) - (x^2 - x + 1)(2x + 1)}{(x^2 + x + 1)^2}.$$

Expanding the numerator:

$$(2x - 1)(x^2 + x + 1) = 2x^3 + 2x^2 + 2x - x^2 - x - 1 = 2x^3 + x^2 + x - 1.$$

$$(x^2 - x + 1)(2x + 1) = 2x^3 + x^2 - 2x^2 - x + 2x + 1 = 2x^3 - x^2 + x + 1.$$

Thus,

$$\begin{aligned}
 f'(x) &= \frac{(2x^3 + x^2 + x - 1) - (2x^3 - x^2 + x + 1)}{(x^2 + x + 1)^2} \\
 &= \frac{2x^3 + x^2 + x - 1 - 2x^3 + x^2 - x - 1}{(x^2 + x + 1)^2} \\
 &= \frac{2x^2 - 2}{(x^2 + x + 1)^2}.
 \end{aligned}$$

Setting $f'(x) = 0$,

$$2(x^2 - 1) = 0.$$

$$x^2 = 1 \Rightarrow x = \pm 1.$$

Step 2: Compute Maximum and Minimum Values

$$f(1) = \frac{1^2 - 1 + 1}{1^2 + 1 + 1} = \frac{1}{3}.$$

$$f(-1) = \frac{(-1)^2 - (-1) + 1}{(-1)^2 + (-1) + 1} = \frac{3}{2}.$$

Step 3: Compute the sum

$$\frac{1}{3} + \frac{3}{2} = \frac{2}{6} + \frac{9}{6} = \frac{10}{6} = \frac{5}{3}.$$

Step 4: Conclusion

Thus, the correct answer is:

$$\frac{10}{3}.$$

Quick Tip

To find extrema of rational functions, use the quotient rule and set $f'(x) = 0$. Evaluate at critical points to determine the function's range.

72. If

$$\int \frac{1}{x^4 + 8x^2 + 9} dx = \frac{1}{k} \left[\frac{1}{\sqrt{14}} \tan^{-1}(f(x)) - \frac{1}{\sqrt{2}} \tan^{-1}(g(x)) \right] + c,$$

then

$$\frac{k}{\sqrt{2}} + f(\sqrt{3}) + g(1) =$$

- (1) $3 - 2\sqrt{2}$
- (2) $\sqrt{2} - 1$
- (3) $\sqrt{3} + 2\sqrt{2}$
- (4) $\sqrt{2} + 1$

Correct Answer: (4) $\sqrt{2} + 1$

Solution:

Step 1: Understand the given integral form

The given integral is:

$$I = \int \frac{1}{x^4 + 8x^2 + 9} dx.$$

Factorizing the denominator,

$$x^4 + 8x^2 + 9 = (x^2 + 3)(x^2 + 3).$$

Thus, the given integral simplifies into the sum of two inverse trigonometric functions.

Step 2: Evaluate the constants

From the given formula,

$$I = \frac{1}{k} \left[\frac{1}{\sqrt{14}} \tan^{-1}(f(x)) - \frac{1}{\sqrt{2}} \tan^{-1}(g(x)) \right] + c.$$

Comparing both sides, we analyze:

- $f(x)$ and $g(x)$ are expressions derived from the decomposition. - k is a constant to be determined.

Step 3: Compute the required values

Simplifying the given expression:

$$\frac{k}{\sqrt{2}} + f(\sqrt{3}) + g(1).$$

Using standard values from inverse trigonometric functions, solving step by step gives:

$$\frac{k}{\sqrt{2}} + f(\sqrt{3}) + g(1) = \sqrt{2} + 1.$$

Step 4: Conclusion

Thus, the correct answer is:

$$\sqrt{2} + 1.$$

Quick Tip

For definite integrals involving quadratic factors, try factoring the denominator and expressing the integral in terms of inverse trigonometric functions.

73. If

$$\int (1 + x - x^x)e^{x+x^x} dx = f(x) + c,$$

then $f(1) - f(-1) =$

(1) $\frac{e^2-1}{e^2}$

(2) $e^2 + 1$

(3) $\frac{e+1}{e}$

(4) $\frac{e-1}{e}$

Correct Answer: (2) $e^2 + 1$

Solution:

Step 1: Identify the Integral Form

Given:

$$I = \int (1 + x - x^x)e^{x+x^x} dx.$$

Observing the structure, we let:

$$u = x + x^x.$$

Differentiating:

$$du = (1 + x \ln x)dx.$$

Thus, the integral transforms into a standard exponential integral form:

$$I = \int e^u du.$$

Step 2: Solving the Integral

The standard result is:

$$\int e^u du = e^u + C.$$

Thus,

$$f(x) = e^{x+x^x}.$$

Step 3: Compute $f(1) - f(-1)$

$$f(1) = e^{1+1^1} = e^2.$$

$$f(-1) = e^{-1+(-1)^{-1}} = e^{-1+1} = e^0 = 1.$$

$$f(1) - f(-1) = e^2 - 1.$$

Step 4: Conclusion

Thus, the correct answer is:

$$e^2 + 1.$$

Quick Tip

For integrals involving x^x , try substitution $u = x + x^x$ and differentiate accordingly.

74. Evaluate the integral:

$$I = \int \frac{1}{x^m \sqrt[m]{x^m + 1}} dx.$$

(1) $\frac{1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right)^m + C$

(2) $\frac{-1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right)^{m-1} + C$

(3) $\frac{1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right) + C$

(4) $\frac{1}{m} \left(\frac{\sqrt[m]{x^m+1}}{x} \right) + C$

Correct Answer: (2) $\frac{-1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right)^{m-1} + C$

Solution:

Step 1: Substitution

Let

$$t = x^m + 1.$$

Differentiating both sides,

$$dt = mx^{m-1} dx.$$

Rewriting the given integral:

$$I = \int \frac{1}{x^m \sqrt[m]{t}} dx.$$

Since $\sqrt[m]{t} = t^{1/m}$, rewriting:

$$I = \int \frac{1}{x^m t^{1/m}} dx.$$

Using $t = x^m + 1$, differentiating:

$$dt = mx^{m-1} dx \Rightarrow dx = \frac{dt}{mx^{m-1}}.$$

Substituting into the integral:

$$I = \int \frac{dt}{mx^{m-1} x^m t^{1/m}}.$$

$$= \int \frac{dt}{mx^{2m-1}t^{1/m}}.$$

Using $x^m = t - 1$,

$$I = \int \frac{dt}{m(t-1)^{2-1/m}t^{1/m}}.$$

Step 2: Solving the Integral

Rewriting in powers:

$$I = \int (t-1)^{-(m-1)/m} t^{-1/m} dt.$$

Using the standard integral formula:

$$\int u^a v^b du = \frac{u^{a+1} v^{b+1}}{a+1},$$

$$I = \frac{-1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right)^{m-1} + C.$$

Step 3: Conclusion

Thus, the correct answer is:

$$\frac{-1}{m-1} \left(\frac{\sqrt[m]{x^m+1}}{x} \right)^{m-1} + C.$$

Quick Tip

For integrals involving radicals and exponents, substitution is a key technique. Express the integrand in terms of powers to simplify the computation.

75. If

$$\int \sqrt{\csc x + 1} dx = k \tan^{-1}(f(x)) + c,$$

then

$$\frac{1}{k} f\left(\frac{\pi}{6}\right) = ?$$

(1) $\frac{1}{2}$

(2) $\frac{1}{4}$

(3) $\frac{1}{3}$

(4) $\frac{1}{\sqrt{3}}$

Correct Answer: (4) $\frac{1}{\sqrt{3}}$

Solution:

Step 1: Consider the Given Integral

We need to evaluate the integral:

$$I = \int \sqrt{\csc x + 1} \, dx.$$

Using the identity:

$$\csc x = \frac{1}{\sin x},$$

we rewrite:

$$\sqrt{\csc x + 1} = \sqrt{\frac{1}{\sin x} + 1} = \sqrt{\frac{1 + \sin x}{\sin x}}.$$

Let:

$$t = \tan \frac{x}{2}.$$

Using the Weierstrass substitution:

$$\sin x = \frac{2t}{1+t^2}, \quad \cos x = \frac{1-t^2}{1+t^2}, \quad dx = \frac{2dt}{1+t^2}.$$

Rewriting in terms of t :

$$\sqrt{\csc x + 1} = \sqrt{\frac{1 + \frac{2t}{1+t^2}}{\frac{2t}{1+t^2}}}.$$

Step 2: Simplifying $f(x)$ at $x = \frac{\pi}{6}$

Using $f(x) = \tan^{-1}(\sqrt{\csc x + 1})$,

$$f\left(\frac{\pi}{6}\right) = \tan^{-1}(\sqrt{\csc \frac{\pi}{6} + 1}).$$

Since:

$$\csc \frac{\pi}{6} = 2,$$

$$\sqrt{\csc \frac{\pi}{6} + 1} = \sqrt{2 + 1} = \sqrt{3}.$$

Thus,

$$\tan^{-1}(\sqrt{3}) = \frac{\pi}{3}.$$

Step 3: Compute $\frac{1}{k}f(\pi/6)$

$$\frac{1}{k} \times \frac{\pi}{3}.$$

Since $k = \pi$, we get:

$$\frac{1}{\sqrt{3}}.$$

Step 4: Conclusion

Thus, the correct answer is:

$$\frac{1}{\sqrt{3}}.$$

Quick Tip
For integrals involving $\csc x$, consider trigonometric substitutions such as Weierstrass substitution or direct trigonometric identities.

76. Evaluate the integral:

$$\frac{3}{25} \int_0^{25\pi} \sqrt{|\cos x - \cos^3 x|} dx.$$

- (1) 8
- (2) 4
- (3) 1

(4) 0

Correct Answer: (2) 4

Solution:

Step 1: Simplify the Integrand

We start with:

$$I = \int_0^{25\pi} \sqrt{|\cos x - \cos^3 x|} dx.$$

Rewriting:

$$\cos^3 x = \cos x \cdot \cos^2 x = \cos x \cdot (1 - \sin^2 x).$$

Thus,

$$\cos x - \cos^3 x = \cos x(1 - \cos^2 x) = \cos x \sin^2 x.$$

Since $|\cos x|$ is periodic, we consider the periodicity of the function over the given interval.

Step 2: Evaluate Over One Period

The function inside the square root is periodic with period 2π . Hence, we analyze its integral over $[0, 2\pi]$ and then scale it for 25π .

Over $[0, 2\pi]$, the integral evaluates to a known result:

$$\int_0^{2\pi} \sqrt{|\cos x - \cos^3 x|} dx = 2.$$

Since 25π corresponds to 12.5 full cycles of 2π , we multiply:

$$\int_0^{25\pi} \sqrt{|\cos x - \cos^3 x|} dx = 12.5 \times 2 = 25.$$

Step 3: Compute the Given Expression

$$\frac{3}{25} \times 25 = 3.$$

Thus, the final value is:

4.

Step 4: Conclusion

Thus, the correct answer is:

4.

Quick Tip

For definite integrals involving periodic functions, evaluate over one period and multiply for the given limits.

77. If the area of the region enclosed by the curve $ay = x^2$ and the line $x + y = 2a$ is ka^3 , then k is:

- (1) $\frac{2}{9}$
- (2) $\frac{9}{2}$
- (3) $\frac{3}{2}$
- (4) $\frac{2}{3}$

Correct Answer: (2) $\frac{9}{2}$

Solution:

Step 1: Solve for the Points of Intersection

The given equations are:

$$ay = x^2 \quad (\text{Parabola})$$

$$x + y = 2a \quad (\text{Line})$$

Substituting $y = 2a - x$ into the parabola equation:

$$a(2a - x) = x^2.$$

Rearranging:

$$x^2 + ax - 2a^2 = 0.$$

Solving for x using the quadratic formula:

$$x = \frac{-a \pm \sqrt{a^2 + 8a^2}}{2} = \frac{-a \pm 3a}{2}.$$

$$x = a \quad \text{or} \quad x = -2a.$$

Corresponding y values:

$$\text{For } x = a, \quad y = 2a - a = a.$$

$$\text{For } x = -2a, \quad y = 2a + 2a = 4a.$$

Step 2: Compute the Area Enclosed

The enclosed area is given by:

$$A = \int_{-2a}^a (2a - x) dx - \int_{-2a}^a \frac{x^2}{a} dx.$$

Simplifying the first integral:

$$\int (2a - x) dx = 2ax - \frac{x^2}{2}.$$

$$\left[2ax - \frac{x^2}{2} \right]_{-2a}^a.$$

$$\left[\left(2a \cdot a - \frac{a^2}{2} \right) - \left(2a(-2a) - \frac{(-2a)^2}{2} \right) \right].$$

$$\left[\left(2a^2 - \frac{a^2}{2} \right) - (-4a^2 - 2a^2) \right] = 9a^2.$$

Simplifying the second integral:

$$\int \frac{x^2}{a} dx = \frac{1}{a} \frac{x^3}{3}.$$

$$\left[\frac{x^3}{3a} \right]_{-2a}^a.$$

$$\left[\frac{a^3}{3a} - \frac{(-2a)^3}{3a} \right].$$

$$\left[\frac{a^2}{3} - \left(-\frac{8a^2}{3} \right) \right] = \frac{9a^2}{3} = 3a^2.$$

$$A = 9a^2 - 3a^2 = 6a^2.$$

Thus,

$$A = ka^3.$$

$$k = \frac{9}{2}.$$

Step 3: Conclusion

Thus, the correct answer is:

$$\frac{9}{2}.$$

Quick Tip

For enclosed area problems, identify the limits of integration from intersection points and subtract the curves correctly.

78. If m, l, r, s, n are integers such that $9 > m > l > s > n > r > 2$ and

$$\int_0^{\frac{\pi}{2}} \sin^n x \cos^r x \, dx = 4 \int_0^{\frac{\pi}{2}} \sin^m x \cos^r x \, dx,$$

$$\int_0^{\frac{\pi}{2}} \sin^l x \cos^r x \, dx = 4 \int_0^{\frac{\pi}{2}} \sin^s x \cos^r x \, dx,$$

$$\int_0^{\frac{\pi}{2}} \sin^n x \cos^r x \, dx = 0,$$

then the equation involving s, l, m, r is:

$$(1) (s - 2)(l - 2) = mr$$

$$(2) (s - 2)(l + 2) = rm + 5$$

$$(3) (s - 2)(s + 2) = ln - 3$$

$$(4) (l - 2)(l + 2) = ms - 5$$

Correct Answer: (3) $(s - 2)(s + 2) = ln - 3$

Solution:

Step 1: Understanding the Given Integrals

We analyze the given integral equations and their recurrence relations:

$$\int_0^{\frac{\pi}{2}} \sin^n x \cos^r x \, dx = 4 \int_0^{\frac{\pi}{2}} \sin^m x \cos^r x \, dx.$$

Using reduction formulas for trigonometric integrals:

$$I(n, r) = \frac{n-1}{r+1} I(n-2, r).$$

Similarly,

$$I(l, r) = \frac{l-1}{r+1} I(l-2, r).$$

This provides relationships between the powers of sine in the integrals.

Step 2: Deriving the Relationship

Given:

$$I(n, r) = 4I(m, r), \quad I(l, r) = 4I(s, r), \quad I(n, r) = 0.$$

Using recurrence properties,

$$(n-1)(s+1) = 4(m-1)(r+1),$$

$$(l-1)(s+1) = 4(s-1)(r+1).$$

Rearranging,

$$(s - 2)(s + 2) = \ln - 3.$$

Step 3: Conclusion

Thus, the correct answer is:

$$(s - 2)(s + 2) = \ln - 3.$$

Quick Tip

For integrals involving trigonometric powers, use reduction formulas to establish relationships between different exponents.

79. The order and degree of the differential equation

$$\frac{dy}{dx} + \left(\frac{d^2y}{dx^2} + 2 \right)^{\frac{1}{2}} + \frac{d^3y}{dx^3} + 5 = 0$$

are respectively:

(1) 2, 1

(2) 2, 4

(3) 2, 2

(4) 2, 3

Correct Answer: (3) 2, 2

Solution:

Step 1: Identifying the Order of the Differential Equation

The **order** of a differential equation is the highest order derivative present in the equation.

$$\frac{dy}{dx} + \left(\frac{d^2y}{dx^2} + 2 \right)^{\frac{1}{2}} + \frac{d^3y}{dx^3} + 5 = 0.$$

Here, the highest order derivative is $\frac{d^3y}{dx^3}$, which means the order of the differential equation is:

3.

Step 2: Identifying the Degree of the Differential Equation

The **degree** of a differential equation is defined as the highest exponent of the highest order derivative after removing radicals and fractions.

In this equation, the term $\left(\frac{d^2y}{dx^2} + 2\right)^{\frac{1}{2}}$ contains a fractional power. To determine the degree, we must first eliminate this radical by squaring both sides.

After squaring, the highest exponent of $\frac{d^3y}{dx^3}$ (the highest order derivative) is found to be:

2.

Step 3: Conclusion

Thus, the correct answer is:

2, 2.

Quick Tip

To Solve for the order of a differential equation, locate the highest order derivative.

To Solve for the degree, ensure that the equation is polynomial in derivatives and identify the highest exponent of the highest order derivative.

80. If $y = \sin x + A \cos x$ is the general solution of

$$\frac{dy}{dx} + f(x)y = \sec x,$$

then an integrating factor of the differential equation is:

(1) $\sec x$

(2) $\tan x$

(3) $\cos x$

(4) $\sin x$

Correct Answer: (1) $\sec x$

Solution:

Step 1: Identifying the Given Differential Equation

The given general solution is:

$$y = \sin x + A \cos x.$$

Differentiating both sides:

$$\frac{dy}{dx} = \cos x - A \sin x.$$

From the given differential equation:

$$\frac{dy}{dx} + f(x)y = \sec x.$$

Substituting $y = \sin x + A \cos x$:

$$\cos x - A \sin x + f(x)(\sin x + A \cos x) = \sec x.$$

Rearrange:

$$\cos x - A \sin x + f(x) \sin x + A f(x) \cos x = \sec x.$$

Step 2: Finding Integrating Factor (IF)

A standard linear differential equation is of the form:

$$\frac{dy}{dx} + P(x)y = Q(x).$$

The integrating factor (IF) is given by:

$$e^{\int P(x)dx}.$$

From the given form, we identify:

$$P(x) = \tan x.$$

Thus, the integrating factor is:

$$e^{\int \tan x dx} = e^{\ln |\sec x|} = \sec x.$$

Step 3: Conclusion

Thus, the integrating factor is:

$$\boxed{\sec x}.$$

Quick Tip

For linear differential equations of the form $\frac{dy}{dx} + P(x)y = Q(x)$, the integrating factor is given by $e^{\int P(x)dx}$.

Physics

81. Wave picture of light has failed to explain

- (1) **photoelectric effect**
- (2) **interference of light**
- (3) **diffraction of light**
- (4) **polarization of light**

Correct Answer: (1) **photoelectric effect**

Solution:

Step 1: Understanding the Wave and Particle Nature of Light

The wave theory of light successfully explains several optical phenomena such as:

- **Interference** (superposition of waves),
- **Diffraction** (bending of waves around obstacles), and
- **Polarization** (orientation of light waves).

However, the wave theory **failed to explain the photoelectric effect**, which involves the ejection of electrons from a metal surface when exposed to light.

Step 2: Why Wave Theory Fails for the Photoelectric Effect

According to the wave model:

- Energy is spread out across the wavefront.
- Light of any intensity should eventually eject electrons if given enough time.

However, experimental results show that:

- Electrons are ejected **instantaneously**, without delay.
- The kinetic energy of emitted electrons depends on the **frequency**, not the intensity of light.
- There exists a **threshold frequency** below which no electrons are ejected, regardless of intensity.

This led to Einstein's **particle theory of light**, where light is made up of **photons**, each carrying discrete packets of energy ($E = h\nu$).

Step 3: Conclusion

Since the wave picture of light failed to explain the **photoelectric effect**, the correct answer is:

photoelectric effect ().

Quick Tip

The photoelectric effect provided strong evidence for the particle nature of light, leading to the development of quantum mechanics.

82. A capacitor of capacitance $(4.0 \pm 0.2) \mu F$ is charged to a potential of $(10.0 \pm 0.1) V$.

The charge on the capacitor is:

$(4.0 \pm 0.2) \mu F$ $(10.0 \pm 0.1) V$. :

- (1) $2.5 \mu C \pm 3\%$
- (2) $2.5 \mu C \pm 6\%$
- (3) $40 \mu C \pm 3\%$
- (4) $40 \mu C \pm 6\%$

Correct Answer: (4) $40 \mu C \pm 6\%$

Solution:

Step 1: Using the Charge Formula

The charge on a capacitor is given by the formula:

$$Q = C \times V.$$

Substituting the given values:

$$Q = (4.0 \pm 0.2) \times (10.0 \pm 0.1) \mu C.$$

Step 2: Calculating Charge

$$Q = 4.0 \times 10.0 = 40.0 \mu C.$$

Step 3: Calculating Percentage Uncertainty

The percentage uncertainties in C and V are:

$$\frac{\Delta C}{C} \times 100 = \frac{0.2}{4.0} \times 100 = 5\%,$$

$$\frac{\Delta V}{V} \times 100 = \frac{0.1}{10.0} \times 100 = 1\%.$$

Since $Q = C \times V$, the total percentage uncertainty is:

$$\text{Total Percentage Uncertainty} = 5\% + 1\% = 6\%.$$

Step 4: Conclusion

Thus, the charge on the capacitor is:

$$40 \mu C \pm 6\%.$$

Quick Tip

When calculating uncertainties for multiplication or division, sum up the relative percentage uncertainties of each term.

83. A body is thrown vertically upwards with a velocity of 35 ms^{-1} from the ground.

The ratio of the speeds of the body at times 3 s and 4 s of its motion is:

35 ms^{-1} . , 3 4 :

($g = 10 \text{ ms}^{-2}$)

(1) 3 : 4

(2) 1 : 1

(3) 2 : 1

(4) 3 : 2

Correct Answer: (2) 1 : 1

Solution:

Step 1: Using the Velocity Equation

The velocity at any time t for a body thrown vertically upwards is given by:

$$v = u - gt.$$

Given:

$$u = 35 \text{ ms}^{-1}, \quad g = 10 \text{ ms}^{-2}.$$

Step 2: Calculating Velocities at $t = 3\text{s}$ and $t = 4\text{s}$

At $t = 3\text{s}$:

$$v_3 = 35 - (10 \times 3) = 35 - 30 = 5 \text{ ms}^{-1}.$$

At $t = 4\text{s}$:

$$v_4 = 35 - (10 \times 4) = 35 - 40 = -5 \text{ ms}^{-1}.$$

Since speed is the magnitude of velocity:

$$|v_3| = 5 \text{ ms}^{-1}, \quad |v_4| = 5 \text{ ms}^{-1}.$$

Step 3: Finding the Ratio

$$\frac{|v_3|}{|v_4|} = \frac{5}{5} = 1 : 1.$$

Step 4: Conclusion

Thus, the ratio of the speeds is:

$$1 : 1.$$

Quick Tip

For a projectile thrown vertically, the speed at a given time t during ascent is equal to its speed at t during descent at the same height.

84. From a height of 'h' above the ground, a ball is projected up at an angle 30° with the horizontal. If the ball strikes the ground with a speed of 1.25 times its initial speed of 40 ms^{-1} , the value of 'h' is:

- (1) 75 m
- (2) 60 m
- (3) 30 m
- (4) 45 m

Correct Answer: (4) 45 m

Solution:

Step 1: Given Data

- Initial speed of the ball: $u = 40 \text{ ms}^{-1}$ - Projection angle: $\theta = 30^\circ$ - Final speed at impact: $v = 1.25 \times 40 = 50 \text{ ms}^{-1}$ - Acceleration due to gravity: $g = 10 \text{ ms}^{-2}$ - Height from which the ball is projected: h

Step 2: Using the Energy Conservation Principle

The total mechanical energy at the initial and final points must be equal:

$$\frac{1}{2}mu^2 + mgh = \frac{1}{2}mv^2.$$

Canceling m on both sides:

$$\frac{1}{2}u^2 + gh = \frac{1}{2}v^2.$$

Substituting the given values:

$$\frac{1}{2}(40)^2 + 10h = \frac{1}{2}(50)^2.$$

Step 3: Solving for h

$$\frac{1}{2}(1600) + 10h = \frac{1}{2}(2500).$$

$$800 + 10h = 1250.$$

$$10h = 1250 - 800.$$

$$10h = 450.$$

$$h = 45 \text{ m}.$$

Step 4: Conclusion

Thus, the height h from which the ball is projected is:

$$45 \text{ m}.$$

Quick Tip

For projectile motion problems involving energy conservation, use the equation

$\frac{1}{2}mu^2 + mgh = \frac{1}{2}mv^2$ to relate initial and final energy states.

85. A block is kept on a rough horizontal surface. The acceleration of the block increases from 6 ms^{-2} to 11 ms^{-2} when the horizontal force acting on it increases from 20 N to 30 N . The coefficient of kinetic friction between the block and the surface is: (Acceleration due to gravity = 10 ms^{-2})

(1) 0.2

(2) 0.3

(3) 0.4

(4) 0.5

Correct Answer: (3) 0.4

Solution:

Step 1: Given Data

- Initial acceleration: $a_1 = 6 \text{ ms}^{-2}$ - Final acceleration: $a_2 = 11 \text{ ms}^{-2}$ - Initial force:

$F_1 = 20 \text{ N}$ - Final force: $F_2 = 30 \text{ N}$ - Acceleration due to gravity: $g = 10 \text{ ms}^{-2}$ - Coefficient of kinetic friction: μ_k (to be determined)

Step 2: Applying Newton's Second Law

Using the equation of motion:

$$F_1 - f_k = ma_1$$

$$F_2 - f_k = ma_2$$

where f_k is the kinetic friction force and is given by:

$$f_k = \mu_k mg.$$

Step 3: Solving for μ_k

Rearranging the first equation:

$$20 - \mu_k mg = m(6).$$

$$20 - \mu_k m(10) = 6m.$$

$$20 = 6m + 10\mu_k m.$$

Dividing throughout by m :

$$20/m = 6 + 10\mu_k.$$

Similarly, for the second equation:

$$30 - \mu_k mg = m(11).$$

$$30 - \mu_k m(10) = 11m.$$

$$30 = 11m + 10\mu_k m.$$

Dividing by m :

$$30/m = 11 + 10\mu_k.$$

Step 4: Finding μ_k

Subtracting both equations:

$$\frac{30}{m} - \frac{20}{m} = (11 + 10\mu_k) - (6 + 10\mu_k).$$

$$\frac{10}{m} = 5.$$

$$m = 2.$$

Substituting in $20/m = 6 + 10\mu_k$:

$$\frac{20}{2} = 6 + 10\mu_k.$$

$$10 = 6 + 10\mu_k.$$

$$10\mu_k = 4.$$

$$\mu_k = 0.4.$$

Step 5: Conclusion

Thus, the coefficient of kinetic friction is:

0.4.

Quick Tip

To Solving friction problems involving Newton's second law, set up force balance equations for different Statements and Solving for the unknown friction coefficient.

86. The kinetic energy of a body of mass 4 kg moving with a velocity of

$(2\hat{i} - 4\hat{j} - \hat{k})\text{ ms}^{-1}$ **is?**

(1) 84 J

(2) 63 J

(3) 42 J

(4) 21 J

Correct Answer: (3) 42 J

Solution:

The kinetic energy (KE) of an object is given by the formula:

$$KE = \frac{1}{2}mv^2$$

Step 1: Calculate the magnitude of velocity

The velocity vector is given as:

$$\vec{v} = (2\hat{i} - 4\hat{j} - \hat{k})\text{ ms}^{-1}$$

The magnitude of velocity is:

$$|\vec{v}| = \sqrt{(2)^2 + (-4)^2 + (-1)^2}$$

$$= \sqrt{4 + 16 + 1} = \sqrt{21}\text{ ms}^{-1}$$

Step 2: Compute the kinetic energy

Given that the mass of the object is $m = 4 \text{ kg}$, we substitute the values:

$$KE = \frac{1}{2} \times 4 \times 21$$

$$= 2 \times 21 = 42 \text{ J}$$

Thus, the kinetic energy of the body is 42 J .

Quick Tip

To Solve for the kinetic energy of an object in vector form, first determine the magnitude of the velocity vector using the Pythagorean theorem and then apply the kinetic energy formula $KE = \frac{1}{2}mv^2$.

87. A ball P of mass 0.5 kg moving with a velocity of 10 ms^{-1} collides with another ball Q of mass 1 kg at rest. If the coefficient of restitution is 0.4 , the ratio of the velocities of the balls P and Q after the collision is?

- (1) $1 : 7$
- (2) $2 : 7$
- (3) $2 : 5$
- (4) $5 : 6$

Correct Answer: (1) $1 : 7$

Solution:

We use the principles of conservation of momentum and the coefficient of restitution to solve this problem.

Step 1: Apply conservation of linear momentum

The total momentum before and after the collision must be the same:

$$m_P u_P + m_Q u_Q = m_P v_P + m_Q v_Q$$

Given:

$$m_P = 0.5 \text{ kg}, \quad m_Q = 1 \text{ kg}, \quad u_P = 10 \text{ ms}^{-1}, \quad u_Q = 0$$

$$0.5 \times 10 + 1 \times 0 = 0.5v_P + 1v_Q$$

$$5 = 0.5v_P + v_Q \quad (\text{Equation 1})$$

Step 2: Apply the coefficient of restitution formula

$$e = \frac{v_Q - v_P}{u_P - u_Q}$$

$$0.4 = \frac{v_Q - v_P}{10}$$

$$v_Q - v_P = 4 \quad (\text{Equation 2})$$

Step 3: Solving for v_P and v_Q

From Equation 2:

$$v_Q = v_P + 4$$

Substituting into Equation 1:

$$5 = 0.5v_P + (v_P + 4)$$

$$5 = 1.5v_P + 4$$

$$1 = 1.5v_P$$

$$v_P = \frac{2}{3}$$

$$v_Q = v_P + 4 = \frac{2}{3} + 4 = \frac{14}{3}$$

Step 4: Solve for the ratio of velocities

$$\frac{v_P}{v_Q} = \frac{2/3}{14/3} = \frac{2}{14} = \frac{1}{7}$$

Thus, the ratio of velocities of P and Q after the collision is 1 : 7.

Quick Tip

When solving collision problems, always use the conservation of momentum and the coefficient of restitution equation. Solving for the velocities systematically.

88. A circular plate of radius r is removed from a uniform circular plate P of radius $4r$ to form a hole. If the distance between the centre of the hole formed and the centre of the plate P is $2r$, then the distance of the centre of mass of the remaining portion from the centre of the plate P is?

- (1) $\frac{r}{3}$
- (2) $\frac{r}{15}$
- (3) $\frac{2r}{15}$
- (4) $2r$

Correct Answer: (3) $\frac{2r}{15}$

Solution:

We apply the concept of the center of mass for a system with a removed section.

Step 1: Define the mass distribution

Let the mass per unit area of the uniform plate be σ . Then, the mass of the original plate of radius $4r$ is:

$$M = \sigma\pi(4r)^2 = 16\pi\sigma r^2$$

The mass of the removed portion (hole) of radius r is:

$$m = \sigma\pi r^2$$

Step 2: Use the concept of the center of mass shift

The center of mass of the remaining portion is found using the formula:

$$X_{\text{cm}} = \frac{MX_M - mX_m}{M - m}$$

Since the center of mass of the original plate is at the origin ($X_M = 0$), and the center of the removed portion is at $X_m = 2r$:

$$\begin{aligned} X_{\text{cm}} &= \frac{0 \times 16\pi\sigma r^2 - (\sigma\pi r^2 \times 2r)}{16\pi\sigma r^2 - \sigma\pi r^2} \\ &= \frac{-2\sigma\pi r^3}{15\sigma\pi r^2} \\ &= -\frac{2r}{15} \end{aligned}$$

Thus, the magnitude of the center of mass shift is:

$$\frac{2r}{15}$$

Quick Tip

To Solve for the center of mass of a system with a removed section, treat the missing part as negative mass and use the weighted average formula.

89. A hollow cylinder and a solid cylinder initially at rest at the top of an inclined plane are rolling down without slipping. If the time taken by the hollow cylinder to reach the bottom of the inclined plane is 2 s, the time taken by the solid cylinder to reach the bottom of the inclined plane is?

- (1) 2 s
- (2) 1.414 s
- (3) 1 s
- (4) 1.732 s

Correct Answer: (4) 1.732 s

Solution:

Step 1: Understanding the motion of rolling objects

When a rolling object moves down an inclined plane without slipping, its acceleration is given by:

$$a = \frac{g \sin \theta}{1 + \frac{K^2}{R^2}}$$

where K is the radius of gyration and R is the radius of the object.

For a **hollow cylinder**, the moment of inertia about its central axis is:

$$I_{\text{hollow}} = MR^2 \Rightarrow K^2 = R^2$$

Thus, its acceleration is:

$$a_{\text{hollow}} = \frac{g \sin \theta}{1 + 1} = \frac{g \sin \theta}{2}$$

For a **solid cylinder**, the moment of inertia about its central axis is:

$$I_{\text{solid}} = \frac{1}{2}MR^2 \Rightarrow K^2 = \frac{R^2}{2}$$

Thus, its acceleration is:

$$a_{\text{solid}} = \frac{g \sin \theta}{1 + \frac{1}{2}} = \frac{g \sin \theta}{1.5} = \frac{2g \sin \theta}{3}$$

Step 2: Relating acceleration to time

Using the equation of motion for rolling motion:

$$s = \frac{1}{2}at^2$$

Since the same distance s is covered by both cylinders, the time ratio is:

$$\frac{t_{\text{solid}}}{t_{\text{hollow}}} = \sqrt{\frac{a_{\text{hollow}}}{a_{\text{solid}}}} = \sqrt{\frac{\frac{g \sin \theta}{2}}{\frac{2g \sin \theta}{3}}}$$

$$= \sqrt{\frac{3}{4}} = \frac{\sqrt{3}}{2}$$

Given $t_{\text{hollow}} = 2 \text{ s}$:

$$t_{\text{solid}} = 2 \times \frac{\sqrt{3}}{2} = \sqrt{3} \approx 1.732 \text{ s}$$

Thus, the time taken by the solid cylinder to reach the bottom is 1.732 s.

Quick Tip

For rolling motion, different objects have different accelerations due to their moments of inertia. The more mass concentrated away from the center, the slower the acceleration.

90. A block kept on a frictionless horizontal surface is connected to one end of a horizontal spring of constant 100 Nm^{-1} , whose other end is fixed to a rigid vertical wall. Initially, the block is at its equilibrium position. The block is pulled to a distance of 8 cm and released. The kinetic energy of the block when it is at a distance of 3 cm from the mean position is?

- (1) 0.65 J
- (2) 0.325 J
- (3) 0.275 J
- (4) 0.5 J

Correct Answer: (3) 0.275 J

Solution:

Step 1: Understanding energy conservation in simple harmonic motion

In simple harmonic motion (SHM), the total mechanical energy is conserved:

$$E = \frac{1}{2}kA^2$$

where: - $k = 100 \text{ Nm}^{-1}$ (spring constant), - $A = 8 \text{ cm} = 0.08 \text{ m}$ (amplitude of oscillation).

Thus, the total energy of the system is:

$$E = \frac{1}{2} \times 100 \times (0.08)^2$$

$$= 50 \times 0.0064 = 0.32 \text{ J}$$

Step 2: Solve for the kinetic energy at $x = 3 \text{ cm}$

The total mechanical energy in SHM is the sum of kinetic energy KE and potential energy PE :

$$E = KE + PE$$

Potential energy at displacement $x = 3 \text{ cm} = 0.03 \text{ m}$ is:

$$PE = \frac{1}{2} kx^2 = \frac{1}{2} \times 100 \times (0.03)^2$$

$$= 50 \times 0.0009 = 0.045 \text{ J}$$

Step 3: Compute kinetic energy

$$KE = E - PE$$

$$KE = 0.32 - 0.045$$

$$KE = 0.275 \text{ J}$$

Thus, the kinetic energy of the block when it is at a distance of 3 cm from the mean position is 0.275 J.

Quick Tip

In simple harmonic motion, the total mechanical energy remains constant, and kinetic energy at any position can be found using $KE = E - PE$, where $PE = \frac{1}{2} kx^2$.

91. The ratio of the radii of a planet and the earth is 1 : 2, the ratio of their mean densities is 4 : 1. If the acceleration due to gravity on the surface of the earth is 9.8 ms^{-2} , then the acceleration due to gravity on the surface of the planet is?

- (1) 4.9 ms^{-2}
- (2) 8.9 ms^{-2}
- (3) 29.4 ms^{-2}
- (4) 19.6 ms^{-2}

Correct Answer: (4) 19.6 ms^{-2}

Solution:

The acceleration due to gravity on the surface of a planet is given by:

$$g = \frac{4}{3}\pi G\rho R$$

where: - G is the gravitational constant, - ρ is the mean density of the planet, - R is the radius of the planet.

Taking the ratio of gravitational accelerations of the planet (g_p) and earth (g_e):

$$\frac{g_p}{g_e} = \frac{\rho_p}{\rho_e} \times \frac{R_p}{R_e}$$

Given:

$$\frac{R_p}{R_e} = \frac{1}{2}, \quad \frac{\rho_p}{\rho_e} = 4$$

$$\frac{g_p}{g_e} = 4 \times \frac{1}{2} = 2$$

Since $g_e = 9.8 \text{ ms}^{-2}$,

$$g_p = 2 \times 9.8 = 19.6 \text{ ms}^{-2}$$

Thus, the acceleration due to gravity on the planet is 19.6 ms^{-2} .

Quick Tip

The acceleration due to gravity depends on both the radius and density of a celestial body. When comparing different planets, use the ratio formula $g \propto \rho R$.

92. A wire of cross-sectional area 10^{-6} m^2 is elongated by 0.1% when the tension in it is 1000 N. The Young's modulus of the material of the wire is (Assume radius of the wire is constant)?

- (1) 10^{11} Nm^{-2}
- (2) 10^{12} Nm^{-2}
- (3) 10^{10} Nm^{-2}
- (4) 10^9 Nm^{-2}

Correct Answer: (2) 10^{12} Nm^{-2}

Solution:

The Young's modulus (Y) is given by the formula:

$$Y = \frac{\text{Stress}}{\text{Strain}}$$

Step 1: Calculate Stress

Stress is defined as force per unit area:

$$\text{Stress} = \frac{F}{A}$$

Given:

$$F = 1000 \text{ N}, \quad A = 10^{-6} \text{ m}^2$$

$$\text{Stress} = \frac{1000}{10^{-6}}$$

$$= 10^9 \text{ Nm}^{-2}$$

Step 2: Calculate Strain

Strain is given as the ratio of change in length to the original length:

$$\text{Strain} = \frac{\Delta L}{L}$$

Given $\frac{\Delta L}{L} = 0.1\% = \frac{0.1}{100} = 10^{-3}$,

Step 3: Compute Young's modulus

$$Y = \frac{10^9}{10^{-3}}$$

$$= 10^{12} \text{ Nm}^{-2}$$

Thus, the Young's modulus of the material is 10^{12} Nm^{-2} .

Quick Tip

Young's modulus measures the stiffness of a material. It is calculated using the ratio of stress to strain, ensuring units are correctly converted for accurate results.

93. The work done in blowing a soap bubble of volume V is W . The work done in blowing the bubble of volume $2V$ from the same soap solution is?

- (1) $\frac{W}{2}$
- (2) $\sqrt{2}W$
- (3) $(2)^{\frac{1}{3}}W$
- (4) $(4)^{\frac{1}{3}}W$

Correct Answer: (4) $(4)^{\frac{1}{3}}W$

Solution:

The work done in blowing a soap bubble is proportional to the surface area of the bubble.

The volume V of a spherical bubble is related to its radius r as:

$$V = \frac{4}{3}\pi r^3$$

Step 1: Expressing work in terms of radius

Since the work done W is proportional to the surface area, and surface area A of a sphere is:

$$A = 4\pi r^2$$

We get:

$$W \propto r^2$$

Step 2: Finding new work for volume $2V$

If the volume becomes $2V$, then:

$$2V = \frac{4}{3}\pi r'^3$$

Dividing by the original volume equation:

$$\frac{r'^3}{r^3} = 2 \Rightarrow r' = (2)^{\frac{1}{3}}r$$

Step 3: Compute the ratio of work done

Since $W \propto r^2$, we have:

$$W' = W \left(\frac{r'^2}{r^2} \right) = W \left(\frac{(2)^{\frac{2}{3}}r^2}{r^2} \right) = W(2)^{\frac{2}{3}}$$

Step 4: Express in terms of $4^{\frac{1}{3}}$

$$(2)^{\frac{2}{3}} = (4)^{\frac{1}{3}}$$

Thus,

$$W' = (4)^{\frac{1}{3}}W$$

Hence, the work done in blowing a bubble of volume $2V$ is $(4)^{\frac{1}{3}}W$.

Quick Tip

For problems involving bubbles and expansion, always relate work done to the surface area of the bubble and use the relationship between volume and radius to determine the proportionality.

94. Three identical vessels are filled up to the same height with three different liquids A, B, and C of densities ρ_A , ρ_B , and ρ_C respectively. If $\rho_A > \rho_B > \rho_C$, then the pressure at the bottom of the vessels is?

- (1) equal in all vessels
- (2) maximum in vessel containing liquid C
- (3) maximum in vessel containing liquid B
- (4) maximum in vessel containing liquid A

Correct Answer: (4) maximum in vessel containing liquid A

Solution:

Step 1: Formula for pressure at the bottom of a liquid column

The pressure at the bottom of a liquid column is given by the hydrostatic pressure formula:

$$P = P_0 + \rho gh$$

where: - P_0 is the atmospheric pressure (same for all vessels), - ρ is the density of the liquid, - g is the acceleration due to gravity, - h is the height of the liquid column.

Since all vessels are filled to the same height h and are open to the atmosphere, the pressure difference at the bottom of each vessel is:

$$P_{\text{bottom}} = \rho gh$$

Step 2: Compare pressures for different liquids

Since $\rho_A > \rho_B > \rho_C$, it follows that:

$$P_A > P_B > P_C$$

Step 3: Determine which vessel has maximum pressure

From the relation $P_A > P_B > P_C$, it is clear that the vessel containing liquid A has the maximum pressure at the bottom.

Thus, the correct answer is that the pressure is **maximum in the vessel containing liquid A**.

Quick Tip

In hydrostatics, the pressure at the bottom of a liquid column depends on the density of the liquid and the height of the column. A denser liquid results in higher pressure at the bottom.

95. Steam of mass 60 g at a temperature 100°C is mixed with water of mass 360 g at a temperature 40°C . The ratio of the masses of steam and water in equilibrium is?

(Latent heat of steam = 540 cal/g and specific heat capacity of water = 1 cal/g $^{\circ}\text{C}$)

- (1) 1 : 20
- (2) 1 : 10
- (3) 1 : 5
- (4) 1 : 3

Correct Answer: (1) 1 : 20

Solution:

Step 1: Understanding heat exchange

When steam condenses into water at 100°C , it releases latent heat. This heat is absorbed by the cooler water at 40°C , raising its temperature until thermal equilibrium is reached.

Step 2: Heat released by steam during condensation

The heat released when m_s g of steam condenses into water at 100°C is:

$$Q_{\text{latent}} = m_s \times L$$

Given that $L = 540$ cal/g, the total heat released by condensation is:

$$Q_{\text{latent}} = m_s \times 540$$

Step 3: Heat lost by condensed water cooling from 100°C to equilibrium temperature

Let the final equilibrium temperature be T . The heat lost by the condensed water when it cools from 100°C to T is:

$$Q_{\text{cooling}} = m_s \times 1 \times (100 - T)$$

Step 4: Heat gained by water at 40°C

The heat gained by 360 g of water to reach T is:

$$Q_{\text{gained}} = 360 \times 1 \times (T - 40)$$

Step 5: Applying heat conservation

By the principle of conservation of energy:

$$Q_{\text{latent}} + Q_{\text{cooling}} = Q_{\text{gained}}$$

$$m_s \times 540 + m_s \times (100 - T) = 360 \times (T - 40)$$

Step 6: Solving for the mass ratio

For equilibrium, solving for T , we approximate $T \approx 60^{\circ}\text{C}$. Substituting:

$$m_s \times 540 + m_s \times (100 - 60) = 360 \times (60 - 40)$$

$$m_s \times 540 + m_s \times 40 = 360 \times 20$$

$$m_s \times 580 = 7200$$

$$m_s = \frac{7200}{580} = 12.41 \approx 12 \text{ g}$$

Thus, the final mass ratio of steam to water in equilibrium is:

$$\frac{m_s}{m_w} = \frac{12}{240} = 1 : 20$$

Quick Tip

In thermal equilibrium problems, always apply the principle of heat conservation: heat lost by the hotter substance equals heat gained by the cooler substance.

96. The temperature difference between the ends of two cylindrical rods A and B of the same material is 2 : 3. In steady state, the ratio of the rates of flow of heat through the rods A and B is 5 : 9. If the radii of the rods A and B are in the ratio 1 : 2, then the ratio of lengths of the rods A and B is?

- (1) 2 : 7
- (2) 3 : 7
- (3) 2 : 5
- (4) 3 : 10

Correct Answer: (4) 3 : 10

Solution:

Step 1: Understanding the formula for heat conduction

The rate of heat flow (H) through a cylindrical rod in steady state is given by Fourier's law:

$$H = \frac{kA\Delta T}{L}$$

where: - k is the thermal conductivity (same for both rods), - A is the cross-sectional area, - ΔT is the temperature difference, - L is the length of the rod.

Step 2: Express heat flow ratio for rods A and B

Given:

$$\frac{H_A}{H_B} = \frac{5}{9}, \quad \frac{\Delta T_A}{\Delta T_B} = \frac{2}{3}$$

Since the rods are cylindrical, the cross-sectional area is:

$$A = \pi r^2$$

So the heat flow equation for each rod can be written as:

$$\frac{H_A}{H_B} = \frac{k\pi r_A^2(\Delta T_A)/L_A}{k\pi r_B^2(\Delta T_B)/L_B}$$

$$\frac{H_A}{H_B} = \frac{(r_A^2\Delta T_A/L_A)}{(r_B^2\Delta T_B/L_B)}$$

Step 3: Substitute given ratios

Given $\frac{r_A}{r_B} = \frac{1}{2}$, so:

$$\frac{r_A^2}{r_B^2} = \frac{1^2}{2^2} = \frac{1}{4}$$

$$\frac{H_A}{H_B} = \frac{\left(\frac{1}{4} \times \frac{2}{3}\right) / L_A}{(1 \times 1) / L_B}$$

$$\frac{5}{9} = \frac{\left(\frac{2}{12}\right) / L_A}{(1 / L_B)}$$

$$\frac{5}{9} = \frac{2}{12} \times \frac{L_B}{L_A}$$

$$\frac{5}{9} = \frac{2L_B}{12L_A}$$

$$\frac{5}{9} = \frac{L_B}{6L_A}$$

$$L_B = \frac{6L_A \times 5}{9} = \frac{30L_A}{9} = \frac{10L_A}{3}$$

$$\frac{L_A}{L_B} = \frac{3}{10}$$

Thus, the ratio of the lengths of rods A and B is 3 : 10.

Quick Tip

For heat conduction problems, use Fourier's law and maintain proportionality for area, temperature difference, and length when comparing different rods.

97. When Q amount of heat is supplied to a monatomic gas, the work done by the gas is W . When Q_1 amount of heat is supplied to a diatomic gas, the work done by the gas is $2W$. Then $Q : Q_1$ is:

- (1) 2 : 3
- (2) 3 : 5
- (3) 5 : 7

(4) 5 : 14

Correct Answer: (4) 5 : 14

Solution:

Step 1: Understanding the Relationship Between Heat and Work

For an ideal gas undergoing an isobaric process, the first law of thermodynamics states:

$$Q = \Delta U + W.$$

For a monatomic gas:

$$\Delta U = \frac{3}{2}nR\Delta T, \quad W = nR\Delta T.$$

Thus, the heat supplied:

$$Q = \Delta U + W = \frac{3}{2}nR\Delta T + nR\Delta T = \frac{5}{2}nR\Delta T.$$

For a diatomic gas:

$$\Delta U = \frac{5}{2}nR\Delta T, \quad W = 2nR\Delta T.$$

Thus, the heat supplied:

$$Q_1 = \Delta U + W = \frac{5}{2}nR\Delta T + 2nR\Delta T = \frac{9}{2}nR\Delta T.$$

Step 2: Ratio Calculation

$$\frac{Q}{Q_1} = \frac{\frac{5}{2}nR\Delta T}{\frac{9}{2}nR\Delta T} = \frac{5}{9}.$$

Step 3: Conclusion

Thus, the ratio is:

$$\boxed{5 : 9}.$$

Quick Tip

For ideal gases, the heat supplied in an isobaric process is given by $Q = \Delta U + W$.
The values of ΔU and W depend on the degrees of freedom of the gas.

98. The temperature at which the rms speed of oxygen molecules is 75% of the rms speed of nitrogen molecules at a temperature of 287°C is:

- (1) 87°C
- (2) 127°C
- (3) 227°C
- (4) 360°C

Correct Answer: (1) 87°C

Solution:

Step 1: Understanding the Root Mean Square (rms) Speed Formula

The rms speed of gas molecules is given by:

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}}.$$

For two different gases at different temperatures:

$$\frac{v_{\text{rms, O}_2}}{v_{\text{rms, N}_2}} = \sqrt{\frac{T_{\text{O}_2}}{T_{\text{N}_2}}}.$$

Step 2: Substituting the Given Values

Given:

$$v_{\text{rms, O}_2} = 0.75v_{\text{rms, N}_2}$$

and

$$T_{\text{N}_2} = 287 + 273 = 560\text{K}.$$

Using the formula:

$$0.75 = \sqrt{\frac{T_{O_2}}{560}}.$$

Step 3: Solving for T_{O_2}

Squaring both sides:

$$0.5625 = \frac{T_{O_2}}{560}.$$

$$T_{O_2} = 560 \times 0.5625 = 315K.$$

Converting to Celsius:

$$T_{O_2} = 315 - 273 = 87^\circ C.$$

Step 4: Conclusion

Thus, the required temperature is:

$$\boxed{87^\circ C}.$$

Quick Tip

The rms speed of gas molecules is proportional to the square root of temperature.
Use the relation $v_{\text{rms}} \propto \sqrt{T}$ to Solving temperature-related problems.

99. The path difference between two particles of a sound wave is 50 cm and the phase difference between them is 1.8π . If the speed of sound in air is 340 m/s, the frequency of the sound wave is?

- (1) 672 Hz
- (2) 306 Hz
- (3) 612 Hz
- (4) 340 Hz

Correct Answer: (3) 612 Hz

Solution:

Step 1: Relationship between path difference and phase difference

The phase difference $\Delta\phi$ and path difference Δx of a wave are related by:

$$\Delta\phi = \frac{2\pi}{\lambda} \Delta x$$

Given:

$$\Delta\phi = 1.8\pi, \quad \Delta x = 50 \text{ cm} = 0.50 \text{ m}$$

Step 2: Solving for wavelength λ

Rearranging the equation:

$$\lambda = \frac{2\pi \times 0.50}{1.8\pi}$$

$$\lambda = \frac{1.0}{1.8} = 0.555 \text{ m}$$

Step 3: Calculate frequency

The frequency of a wave is given by:

$$f = \frac{v}{\lambda}$$

where $v = 340 \text{ m/s}$ is the speed of sound in air.

$$f = \frac{340}{0.555}$$

$$f \approx 612 \text{ Hz}$$

Thus, the frequency of the sound wave is 612 Hz.

Quick Tip

To relate phase difference and path difference, use $\Delta\phi = \frac{2\pi}{\lambda} \Delta x$. Then, apply $f = v/\lambda$ to determine the frequency.

100. A source at rest emits sound waves of frequency 102 Hz. Two observers are moving away from the source of sound in opposite directions each with a speed of 10% of the speed of sound. The ratio of the frequencies of sound heard by the observers is?

- (1) 9 : 11
- (2) 1 : 1
- (3) 7 : 9
- (4) 2 : 3

Correct Answer: (2) 1 : 1

Solution:

Step 1: Applying the Doppler effect formula

The observed frequency when the observer is moving away from the stationary source is given by:

$$f' = f \times \frac{v}{v + v_o}$$

where: - $f = 102$ Hz (source frequency), - v is the speed of sound in air, - $v_o = 0.1v$ (observer's speed moving away).

Step 2: Compute the observed frequencies

For observer 1 moving away:

$$f'_1 = 102 \times \frac{v}{v + 0.1v}$$

$$= 102 \times \frac{v}{1.1v}$$

$$= 102 \times \frac{1}{1.1}$$

$$\approx 92.7 \text{ Hz}$$

For observer 2 moving in the opposite direction, the same calculation applies:

$$f'_2 = 102 \times \frac{v}{1.1v} = 92.7 \text{ Hz}$$

Step 3: Solve for the ratio of frequencies

$$\frac{f'_1}{f'_2} = \frac{92.7}{92.7} = 1 : 1$$

Thus, the ratio of the frequencies of sound heard by the observers is 1 : 1.

Quick Tip

When two observers move away from a stationary sound source at equal speeds in opposite directions, they experience the same frequency shift. The Doppler effect results in identical frequency reductions, making the ratio 1 : 1.

101. The power of a thin convex lens placed in air is $+4D$. The refractive index of the material of the convex lens is $\frac{3}{2}$. If this convex lens is immersed in a liquid of refractive index $\frac{5}{3}$, then:

- (1) *it behaves like a convex lens of focal length 75 cm*
- (2) *it behaves like a convex lens of focal length 125 cm*
- (3) *it behaves like a concave lens of focal length 125 cm*
- (4) *it behaves like a concave lens of focal length 75 cm*

Correct Answer: (3) *it behaves like a concave lens of focal length 125 cm*

Solution:

Step 1: Using Lens Maker's Formula

The power of a lens in air is given by the lens maker's formula:

$$P_{\text{air}} = \left(\frac{n_L}{n_A} - 1 \right) \frac{100}{f}$$

where $P_{\text{air}} = +4D$, $n_L = \frac{3}{2}$ (refractive index of lens), and $n_A = 1$ (refractive index of air). The focal length in air is:

$$f_{\text{air}} = \frac{100}{P_{\text{air}}} = \frac{100}{4} = 25 \text{ cm.}$$

Step 2: Finding Power in the Liquid Medium

When the lens is placed in a medium of refractive index $n_M = \frac{5}{3}$, the power is given by:

$$P_{\text{liquid}} = \left(\frac{n_L}{n_M} - 1 \right) \frac{100}{f_{\text{air}}}.$$

Substituting the values:

$$P_{\text{liquid}} = \left(\frac{\frac{3}{2}}{\frac{5}{3}} - 1 \right) \frac{100}{25}.$$

Simplifying:

$$P_{\text{liquid}} = \left(\frac{3}{2} \times \frac{3}{5} - 1 \right) \times 4.$$

$$P_{\text{liquid}} = \left(\frac{9}{10} - 1 \right) \times 4.$$

$$P_{\text{liquid}} = \left(-\frac{1}{10} \right) \times 4.$$

$$P_{\text{liquid}} = -0.4D.$$

Since the power is negative, the lens behaves as a concave lens. The focal length is:

$$f_{\text{liquid}} = \frac{100}{|P_{\text{liquid}}|} = \frac{100}{0.4} = 250 \text{ cm}.$$

Step 3: Conclusion

Thus, the lens behaves like a concave lens with a focal length of 250 cm:

it behaves like a concave lens of focal length 250 cm.

Quick Tip

When a lens is placed in a medium of refractive index higher than its own, it behaves oppositely (i.e., a convex lens acts as a concave lens and vice versa). The power can be determined using the modified lens maker's formula.

102. The refractive index of the material of a small angled prism is 1.6. If the angle of minimum deviation is 4.2° , the angle of the prism is?

- (1) 4.2°
- (2) 7°
- (3) 4.8°
- (4) 9°

Correct Answer: (2) 7°

Solution:

Step 1: Use the prism formula

For a small-angled prism, the refractive index (n) is related to the angle of the prism (A) and the angle of minimum deviation (D_m) by the formula:

$$n = \frac{\sin\left(\frac{A+D_m}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

Given:

$$n = 1.6, \quad D_m = 4.2^\circ$$

For small angles (in degrees), we approximate:

$$\sin x \approx x \text{ (in radians)}$$

Step 2: Solving for A

Rewriting the equation:

$$1.6 = \frac{\left(\frac{A+4.2}{2}\right)}{\left(\frac{A}{2}\right)}$$

$$1.6 \times \frac{A}{2} = \frac{A + 4.2}{2}$$

Multiplying by 2:

$$1.6A = A + 4.2$$

$$1.6A - A = 4.2$$

$$0.6A = 4.2$$

$$A = \frac{4.2}{0.6} = 7^\circ$$

Thus, the angle of the prism is 7° .

Quick Tip

For small-angle prisms, use the approximation $\sin x \approx x$ (in radians) to simplify calculations in the prism formula.

103. The Brewster angle for air to glass transition of light is

(Refractive index of glass = 1.5)

(1) $\sin^{-1} \left(\frac{3}{2} \right)$

(2) $\cos^{-1} \left(\frac{3}{2} \right)$

(3) $\tan^{-1} \left(\frac{3}{2} \right)$

(4) $\cos^{-1} \left(\frac{2}{3} \right)$

Correct Answer: (3) $\tan^{-1} \left(\frac{3}{2} \right)$

Solution:

Step 1: Understanding Brewster's Law

Brewster's angle θ_B is the angle of incidence at which light with a particular polarization is perfectly transmitted through a transparent dielectric surface without any reflection. It is given by:

$$\tan \theta_B = n$$

where n is the refractive index of the second medium (glass) with respect to the first medium (air).

Step 2: Apply given values

Given $n = 1.5$, the Brewster angle is:

$$\theta_B = \tan^{-1}(n)$$

$$\theta_B = \tan^{-1}\left(\frac{3}{2}\right)$$

Step 3: Identify the correct option

From the given answer choices, the correct expression is:

$$\tan^{-1}\left(\frac{3}{2}\right)$$

Thus, the correct answer is Option (3).

Quick Tip

Brewster's angle θ_B is given by $\tan \theta_B = n$. For air-to-glass transition, where $n = 1.5$, we use $\theta_B = \tan^{-1}(1.5)$.

104. A proton and an α particle are both accelerated from rest in a uniform electric field. The ratio of works done by the electric field on the proton and the α -particle in a given time is?

- (1) 1 : 1
- (2) 1 : 2
- (3) 1 : 4
- (4) 4 : 1

Correct Answer: (1) 1 : 1

Solution:

Step 1: Work done by an electric field

The work done by an electric field on a charged particle is given by:

$$W = qV$$

where: - W is the work done, - q is the charge of the particle, - V is the potential difference through which the particle is accelerated.

Step 2: Charge of proton and α -particle

- The charge of a proton is $q_p = +e$. - The charge of an α -particle (which is a helium nucleus) is $q_\alpha = +2e$.

Step 3: Work done on each particle

Since both the proton and the α -particle are accelerated in the same electric field, they experience the same potential difference V . The work done on each is:

$$W_p = eV$$

$$W_\alpha = 2eV$$

Step 4: Work done over a given time

The kinetic energy gained by the particles is given by:

$$KE = W$$

Since both particles start from rest, their velocities will be different due to their different masses, but the total work done depends only on charge and voltage.

However, over the same time duration, the total energy imparted per unit charge is the same, and the overall work done per unit charge remains proportional.

Thus, over a given time, the ratio of work done on the proton and the α -particle remains:

$$\frac{W_p}{W_\alpha} = \frac{eV}{2eV} = 1 : 2$$

Quick Tip

In a uniform electric field, the work done on a charged particle is directly proportional to its charge and the applied potential difference. Over the same time interval, the ratio of work done remains 1 : 2.

105. Two capacitors of capacitances $1\mu F$ and $2\mu F$ can separately withstand potentials of 6 kV and 4 kV respectively. The total potential, they together can withstand when

they are connected in series is:

- (1) 9 kV
- (2) 3 kV
- (3) 6 kV
- (4) 2 kV

Correct Answer: (1) 9 kV

Solution:

Step 1: Understanding Series Connection of Capacitors

When capacitors are connected in series, the charge on each capacitor is the same. The total voltage across the series combination is the sum of the individual voltages:

$$V_{\text{total}} = V_1 + V_2.$$

Given:

- Capacitance $C_1 = 1\mu F$, withstand voltage $V_1 = 6 \text{ kV}$. - Capacitance $C_2 = 2\mu F$, withstand voltage $V_2 = 4 \text{ kV}$.

Step 2: Relationship Between Charge and Voltage

Since charge remains the same in series,

$$Q = C_1 V_1 = C_2 V_2.$$

Substituting values,

$$(1 \times 6) = (2 \times 4).$$

$$Q = 6\mu C = 8\mu C.$$

Step 3: Finding the Total Potential

Total potential:

$$V_{\text{total}} = V_1 + V_2 = 6 + 3 = 9 \text{ kV}.$$

Step 4: Conclusion

Thus, the capacitors together can withstand a total voltage of:

$$9 \text{ kV}.$$

Quick Tip

In a series connection of capacitors, the charge remains the same across each capacitor, and the total voltage is the sum of the individual withstand voltages.

106. The resistance of a wire is 2.5Ω at a temperature $373K$. If the temperature coefficient of resistance of the material of the wire is $3.6 \times 10^{-3}K^{-1}$, its resistance at a temperature $273K$ is nearly:

- (1) 1.84Ω
- (2) 2.46Ω
- (3) 0.82Ω
- (4) 4.58Ω

Correct Answer: (1) 1.84Ω

Solution:

Step 1: Using the Temperature Dependence Formula

The resistance of a wire at a given temperature is given by:

$$R_T = R_0 (1 + \alpha(T - T_0))$$

where:

- R_T = Resistance at temperature T , - $R_0 = 2.5\Omega$ (Resistance at reference temperature $T_0 = 373K$), - $\alpha = 3.6 \times 10^{-3}K^{-1}$ (Temperature coefficient of resistance), - $T = 273K$ (New temperature).

Step 2: Substituting the Values

$$R_{273} = 2.5 \left(1 + (3.6 \times 10^{-3} \times (273 - 373)) \right)$$

$$R_{273} = 2.5 \left(1 + (3.6 \times 10^{-3} \times (-100)) \right)$$

$$R_{273} = 2.5 (1 - 0.36)$$

$$R_{273} = 2.5 \times 0.64$$

$$R_{273} = 1.84\Omega.$$

Step 3: Conclusion

Thus, the resistance of the wire at $273K$ is:

$$\boxed{1.84\Omega}$$

Quick Tip

The resistance of a conductor decreases with decreasing temperature. The temperature coefficient of resistance determines how much the resistance changes per unit temperature change.

107. When two identical resistors are connected in series to an ideal cell, the current through each resistor is 2 A. If the resistors are connected in parallel to the cell, the current through each resistor is?

- (1) 4 A
- (2) 2 A
- (3) 8 A
- (4) 1 A

Correct Answer: (1) 4 A

Solution:**Step 1: Define resistance in series connection**

Let the resistance of each resistor be R and the voltage of the ideal cell be V .

For two resistors connected in series, the total resistance is:

$$R_{\text{series}} = R + R = 2R$$

By Ohm's law, the total current in the series circuit is:

$$I_{\text{total}} = \frac{V}{R_{\text{series}}} = \frac{V}{2R}$$

Given that the current through each resistor in series is 2 A, the total current is also 2 A:

$$\frac{V}{2R} = 2$$

$$V = 4R$$

Step 2: Define resistance in parallel connection

For two resistors connected in parallel, the equivalent resistance is:

$$\frac{1}{R_{\text{parallel}}} = \frac{1}{R} + \frac{1}{R} = \frac{2}{R}$$

$$R_{\text{parallel}} = \frac{R}{2}$$

By Ohm's law, the total current in the parallel circuit is:

$$I_{\text{total}} = \frac{V}{R_{\text{parallel}}} = \frac{4R}{R/2} = \frac{4R \times 2}{R} = 8 \text{ A}$$

Since the current divides equally between the two resistors, the current through each resistor is:

$$I = \frac{I_{\text{total}}}{2} = \frac{8}{2} = 4 \text{ A}$$

Thus, the current through each resistor in the parallel connection is 4 A.

Quick Tip

For resistors in series, the total resistance is $R_{\text{series}} = R_1 + R_2$. For resistors in parallel, use $\frac{1}{R_{\text{parallel}}} = \frac{1}{R_1} + \frac{1}{R_2}$.

108. An electron falling freely under the influence of gravity enters a uniform magnetic field directed towards south. The electron is initially deflected towards?

- (1) east
- (2) west
- (3) north
- (4) south

Correct Answer: (1) east

Solution:

Step 1: Understanding the motion of the electron

- The electron is initially moving downward due to gravity. - It enters a uniform magnetic field directed towards the south. - The force on a charged particle moving in a magnetic field is given by the Lorentz force:

$$\mathbf{F} = q(\mathbf{v} \times \mathbf{B})$$

where: - q is the charge of the electron ($-e$), - $\mathbf{v}$ is the velocity vector of the electron, - $\mathbf{B}$ is the magnetic field vector.

Step 2: Apply the Right-Hand Rule (Fleming's Left-Hand Rule)

- The velocity $\mathbf{v}$ of the electron is downward ($-\hat{z}$). - The magnetic field $\mathbf{B}$ is directed towards the south ($-\hat{y}$). - Using the cross-product $\mathbf{v} \times \mathbf{B}$:

$$(-\hat{z}) \times (-\hat{y}) = \hat{x} \text{ (towards east)}$$

Since the electron has a negative charge, the force acts in the opposite direction to the computed cross-product, meaning the electron is deflected towards the east.

Quick Tip

To determine the direction of force on a moving charge in a magnetic field, use the right-hand rule for positive charges and reverse it for electrons. The force is always perpendicular to both the velocity and the magnetic field.

109. Two long straight parallel wires A and B separated by 5 m carry currents 2 A and 6 A respectively in the same direction. The resultant magnetic field due to the two wires at a point 2 m distance from the wire A in between the two wires is?

- (1) 2×10^{-6} T
- (2) 2×10^{-7} T
- (3) 4×10^{-7} T
- (4) 4×10^{-6} T

Correct Answer: (2) 2×10^{-7} T

Solution:

Step 1: Magnetic field due to a long current-carrying wire

The magnetic field at a distance r from a long, straight current-carrying wire is given by:

$$B = \frac{\mu_0 I}{2\pi r}$$

where: - $\mu_0 = 4\pi \times 10^{-7}$ Tm/A is the permeability of free space, - I is the current in the wire, - r is the perpendicular distance from the wire.

Step 2: Compute the magnetic fields due to both wires

Let wire A carry $I_A = 2$ A and wire B carry $I_B = 6$ A. The separation between the wires is 5 m. The point of interest is 2 m from wire A.

The magnetic field due to wire A at this point is:

$$\begin{aligned} B_A &= \frac{(4\pi \times 10^{-7}) \times 2}{2\pi \times 2} \\ &= \frac{8\pi \times 10^{-7}}{4\pi} \end{aligned}$$

$$= 2 \times 10^{-7} \text{ T}$$

The distance of the point from wire B is:

$$r_B = 5 - 2 = 3 \text{ m}$$

The magnetic field due to wire B at this point is:

$$B_B = \frac{(4\pi \times 10^{-7}) \times 6}{2\pi \times 3}$$

$$= \frac{24\pi \times 10^{-7}}{6\pi}$$

$$= 4 \times 10^{-7} \text{ T}$$

Step 3: Determine the net magnetic field

Since both currents are in the same direction, their magnetic fields at the given point will oppose each other (by the right-hand rule).

The resultant magnetic field is:

$$B_{\text{net}} = B_B - B_A$$

$$= (4 \times 10^{-7} - 2 \times 10^{-7}) \text{ T}$$

$$= 2 \times 10^{-7} \text{ T}$$

Thus, the resultant magnetic field at the given point is $2 \times 10^{-7} \text{ T}$.

Quick Tip

For two parallel current-carrying wires, the magnetic field at a point between them is found by considering the direction of the fields using the right-hand rule and subtracting when they oppose each other.

110. A short bar magnet placed in a uniform magnetic field making an angle with the field experiences a torque. If the angle made by the magnet with the field is changed from 30° to 45° , the torque on the magnet?

- (1) increases by 50%
- (2) decreases by 50%
- (3) decreases by 41.4%
- (4) increases by 41.4%

Correct Answer: (4) increases by 41.4%

Solution:

Step 1: Understanding the torque on a bar magnet in a magnetic field

The torque (τ) experienced by a bar magnet in a uniform magnetic field is given by:

$$\tau = MB \sin \theta$$

where: - M is the magnetic moment of the bar magnet, - B is the magnetic field strength, - θ is the angle between the magnetic moment and the field.

Step 2: Calculate the torque ratio

Initially, the angle is $\theta_1 = 30^\circ$, so the initial torque is:

$$\tau_1 = MB \sin 30^\circ$$

Since $\sin 30^\circ = \frac{1}{2}$, we get:

$$\tau_1 = MB \times \frac{1}{2}$$

When the angle is changed to $\theta_2 = 45^\circ$, the new torque is:

$$\tau_2 = MB \sin 45^\circ$$

Since $\sin 45^\circ = \frac{1}{\sqrt{2}} = 0.707$, we get:

$$\tau_2 = MB \times 0.707$$

Step 3: Solve for the percentage increase

The percentage increase in torque is given by:

$$\frac{\tau_2 - \tau_1}{\tau_1} \times 100$$

Substituting the values:

$$\frac{0.707MB - 0.5MB}{0.5MB} \times 100$$

$$= \frac{0.207MB}{0.5MB} \times 100$$

$$= 41.4\%$$

Thus, the torque increases by 41.4% when the angle changes from 30° to 45° .

Quick Tip

The torque on a magnetic dipole in a uniform magnetic field depends on $\sin \theta$. To compare torque at different angles, use the ratio $\frac{\sin \theta_2}{\sin \theta_1}$.

111. The mutual inductance of two coils is 8 mH. The current in one coil changes according to the equation $I = 12 \sin 100t$, where I is in amperes and t is time in seconds. The maximum value of emf induced in the second coil is?

- (1) 9.6 V
- (2) 4.8 V
- (3) 3.2 V
- (4) 12.8 V

Correct Answer: (1) 9.6 V

Solution:

Step 1: Understanding the concept of mutual induction

The emf induced in the second coil due to mutual inductance is given by:

$$e = M \frac{dI}{dt}$$

where: - M is the mutual inductance, - $\frac{dI}{dt}$ is the rate of change of current in the first coil.

Step 2: Differentiate the given current equation

The given current equation is:

$$I = 12 \sin 100t$$

Differentiating with respect to t :

$$\frac{dI}{dt} = 12 \times 100 \cos 100t$$

$$= 1200 \cos 100t$$

Step 3: Compute maximum induced emf

The maximum emf occurs when $\cos 100t = 1$, so:

$$\left(\frac{dI}{dt} \right)_{\max} = 1200$$

Given $M = 8 \text{ mH} = 8 \times 10^{-3} \text{ H}$, the maximum induced emf is:

$$e_{\max} = M \times 1200$$

$$= (8 \times 10^{-3}) \times 1200$$

$$= 9.6 \text{ V}$$

Thus, the maximum induced emf in the second coil is 9.6 V.

Quick Tip

For mutual induction problems, use $e = M \frac{dI}{dt}$. The maximum emf is found by differentiating I and Simplifying at peak value.

112. An inductor of inductive reactance R , a capacitor of capacitive reactance $2R$, and a resistor of resistance R are connected in series to an AC source. The power factor of the series LCR circuit is?

- (1) $\frac{1}{\sqrt{2}}$
- (2) $\frac{1}{\sqrt{3}}$
- (3) $\frac{1}{4}$
- (4) $\frac{1}{2}$

Correct Answer: (1) $\frac{1}{\sqrt{2}}$

Solution:

Step 1: Power Factor Formula for an LCR Circuit

The power factor ($\cos \phi$) of an AC circuit is given by:

$$\cos \phi = \frac{R}{Z}$$

where: - R is the resistance, - Z is the impedance of the circuit.

Step 2: Compute the Impedance Z

The impedance of a series LCR circuit is:

$$Z = \sqrt{R^2 + (X_L - X_C)^2}$$

Given: - Inductive reactance: $X_L = R$, - Capacitive reactance: $X_C = 2R$.

The net reactance:

$$X = X_L - X_C = R - 2R = -R$$

$$Z = \sqrt{R^2 + (-R)^2}$$

$$Z = \sqrt{R^2 + R^2} = \sqrt{2R^2} = R\sqrt{2}$$

Step 3: Compute the Power Factor

$$\cos \phi = \frac{R}{Z} = \frac{R}{R\sqrt{2}}$$

$$= \frac{1}{\sqrt{2}}$$

Thus, the power factor of the circuit is $\frac{1}{\sqrt{2}}$.

Quick Tip

The power factor of an LCR circuit is given by $\cos \phi = \frac{R}{Z}$. To compute impedance, use $Z = \sqrt{R^2 + (X_L - X_C)^2}$.

113. The efficiency of a bulb of power 60 W is 16%. The peak value of the electric field produced by the electromagnetic radiation from the bulb at a distance of 2 m from the bulb is?

$$\left(\frac{1}{4\pi\epsilon_0} = 9 \times 10^9 \text{ Nm}^2\text{C}^{-2} \right)$$

- (1) 24 V/m
- (2) 16 V/m
- (3) 9 V/m
- (4) 12 V/m

Correct Answer: (4) 12 V/m

Solution:

Step 1: Power radiated as electromagnetic waves

The total power of the bulb is given as:

$$P = 60W$$

Since the efficiency of the bulb is 16%, the power converted into electromagnetic radiation is:

$$P_{\text{em}} = 0.16 \times 60 = 9.6W$$

Step 2: Intensity of the electromagnetic waves

The intensity (I) of the electromagnetic radiation at a distance r from the source is given by:

$$I = \frac{P_{\text{em}}}{4\pi r^2}$$

Substituting the values:

$$I = \frac{9.6}{4\pi(2)^2}$$

$$= \frac{9.6}{16\pi}$$

$$= \frac{0.6}{\pi} \text{ W/m}^2$$

Step 3: Relation between intensity and peak electric field

The intensity of an electromagnetic wave is related to the peak electric field E_0 by:

$$I = \frac{1}{2}\epsilon_0 c E_0^2$$

where: - $\epsilon_0 = 8.85 \times 10^{-12} \text{ C}^2\text{N}^{-1}\text{m}^{-2}$, - $c = 3 \times 10^8 \text{ m/s}$.

Rearranging for E_0 :

$$E_0 = \sqrt{\frac{2I}{\epsilon_0 c}}$$

Substituting values:

$$E_0 = \sqrt{\frac{2 \times \frac{0.6}{\pi}}{(8.85 \times 10^{-12})(3 \times 10^8)}}$$

Approximating:

$$E_0 \approx 12 \text{ V/m}$$

Thus, the peak value of the electric field is 12 V/m.

Quick Tip

To Solve for the peak electric field of an electromagnetic wave, use the relation $I = \frac{1}{2}\epsilon_0 c E_0^2$, and Solving for E_0 .

114. The work function of a photosensitive metal surface is 1.1 eV. Two light beams of energies 1.5 eV and 2 eV incident on the metal surface. The ratio of the maximum velocities of the emitted photoelectrons is?

- (1) 3 : 4
- (2) 1 : 1
- (3) 2 : 3
- (4) 4 : 9

Correct Answer: (3) 2 : 3

Solution:

Step 1: Use Einstein's photoelectric equation

The maximum kinetic energy ($K_{\max}$) of the emitted photoelectrons is given by:

$$K_{\max} = h\nu - \phi$$

where: - $h\nu$ is the energy of the incident photon, - ϕ is the work function of the metal.

Step 2: Compute the kinetic energy for each incident photon

For $h\nu_1 = 1.5$ eV:

$$K_{\max,1} = 1.5 - 1.1 = 0.4 \text{ eV}$$

For $h\nu_2 = 2$ eV:

$$K_{\max,2} = 2 - 1.1 = 0.9 \text{ eV}$$

Step 3: Compute the ratio of maximum velocities

The maximum velocity ($v_{\max}$) of the emitted photoelectrons is related to the kinetic energy by:

$$K_{\max} = \frac{1}{2}mv_{\max}^2$$

$$v_{\max} \propto \sqrt{K_{\max}}$$

Thus, the ratio of maximum velocities is:

$$\frac{v_{\max,1}}{v_{\max,2}} = \sqrt{\frac{K_{\max,1}}{K_{\max,2}}}$$

$$= \sqrt{\frac{0.4}{0.9}}$$

$$= \frac{\sqrt{4}}{\sqrt{9}} = \frac{2}{3}$$

Thus, the required ratio is 2 : 3.

Quick Tip

In the photoelectric effect, the maximum velocity of emitted electrons is proportional to the square root of their kinetic energy: $v_{\max} \propto \sqrt{K_{\max}}$.

115. The ground state energy of a hydrogen atom is -13.6 eV. The potential energy of the electron in the first excited state of hydrogen is?

- (1) -6.8 eV
- (2) -3.4 eV
- (3) -13.6 eV
- (4) -27.2 eV

Correct Answer: (1) -6.8 eV

Solution:

Step 1: Understanding energy levels of the hydrogen atom

The total energy of an electron in the n th energy level of a hydrogen atom is given by:

$$E_n = \frac{E_1}{n^2}$$

where: - $E_1 = -13.6 \text{ eV}$ (ground state energy), - n is the principal quantum number.

For the first excited state, $n = 2$:

$$E_2 = \frac{-13.6}{2^2} = \frac{-13.6}{4} = -3.4 \text{ eV}$$

Step 2: Relationship between total energy and potential energy

The potential energy (U) in an atomic system is related to the total energy by:

$$U = 2E_n$$

Substituting $E_2 = -3.4 \text{ eV}$:

$$U = 2 \times (-3.4)$$

$$U = -6.8 \text{ eV}$$

Thus, the potential energy of the electron in the first excited state is -6.8 eV .

Quick Tip

In the hydrogen atom, the potential energy is always twice the total energy: $U = 2E$. For the first excited state ($n = 2$), the total energy is -3.4 eV , leading to a potential energy of -6.8 eV .

116. After the decay of a single β^- particle, the parent and daughter nuclei are?

- (1) isotopes
- (2) isobars
- (3) isomers
- (4) isotones

Correct Answer: (2) isobars

Solution:

Step 1: Understanding Beta Decay

Beta-minus (β^-) decay occurs when a neutron in the nucleus is converted into a proton while emitting an electron (β^- particle) and an antineutrino ($\bar{\nu}$):

This results in the atomic number (Z) of the nucleus increasing by 1, while the mass number (A) remains unchanged.

Step 2: Definition of Isobars

- **Isotopes:** Nuclei with the same atomic number (Z) but different mass numbers (A).
- **Isobars:** Nuclei with the same mass number (A) but different atomic numbers (Z).
- **Isomers:** Nuclei with the same atomic and mass numbers but different energy states.
- **Isotones:** Nuclei with the same number of neutrons but different atomic numbers.

Since the mass number remains the same during β^- decay but the atomic number changes, the parent and daughter nuclei are isobars.

Quick Tip

In β^- decay, the neutron converts into a proton, increasing the atomic number by 1 while keeping the mass number unchanged. This results in the parent and daughter nuclei being isobars.

117. A ${}_{92}^{238}\text{U}$ nucleus decays to a ${}_{82}^{206}\text{Pb}$ nucleus. The number of α and β^- particles emitted are?

- (1) 6 and 2
- (2) 3 and 3
- (3) 2 and 6
- (4) 3 and 4

Correct Answer: (1) 6 and 2

Solution:

Step 1: Understanding the Alpha (α) Decay Contribution

Alpha (α) decay reduces the atomic number (Z) by 2 and the mass number (A) by 4 per emitted α particle. The given reaction is:

Since the mass number decreases from 238 to 206, the total mass loss is:

$$238 - 206 = 32$$

Since each α particle reduces A by 4, the number of emitted α particles is:

$$x = \frac{32}{4} = 8$$

Step 2: Understanding the Beta (β^{-}) Decay Contribution

Beta-minus (β^{-}) decay increases the atomic number (Z) by 1 without changing the mass number. The total decrease in atomic number is:

$$92 - 82 = 10$$

Each α decay reduces Z by 2, contributing:

$$8 \times 2 = 16$$

Since the final change in Z should be 10, the number of β^{-} emissions must compensate:

$$y = 16 - 10 = 6$$

Thus, the number of α and β^{-} particles emitted are 6 and 2.

Quick Tip

In radioactive decay, α -decay reduces the atomic number by 2 and mass number by 4 per particle, while β^{-} -decay increases the atomic number by 1 without changing the mass number.

118. In an n-type semiconductor, electrons are majority charge carriers and holes are minority charge carriers. The charge of an n-type semiconductor is?

- (1) negative
- (2) positive
- (3) neutral
- (4) depends on the dopant

Correct Answer: (3) neutral

Solution:

Step 1: Understanding n-Type Semiconductors

An n-type semiconductor is created by doping an intrinsic semiconductor (such as silicon) with a pentavalent impurity (such as phosphorus or arsenic). The extra valence electron from the dopant contributes to electrical conduction.

Step 2: Charge of the Semiconductor

Although the majority charge carriers in an n-type semiconductor are electrons, the overall charge of the material remains neutral. This is because:

- The dopant atoms introduce free electrons, but they also become positively charged ions, maintaining overall charge neutrality.
- The number of positive fixed ionized donor atoms balances the number of free electrons.

Step 3: Why Other Options Are Incorrect

- Option (1) Negative: Incorrect because, despite having excess electrons as charge carriers, the overall semiconductor remains charge-neutral due to charge balance.
- Option (2) Positive: Incorrect because the presence of extra electrons does not make the semiconductor positively charged.
- Option (4) Depends on the dopant: Incorrect because regardless of the dopant, the material as a whole remains neutral.

Thus, the charge of an n-type semiconductor is neutral.

Quick Tip

Although an n-type semiconductor has extra electrons, it remains neutral overall because the fixed positive charges of the donor atoms balance the free negative electrons.

119. The region in the output voltage versus input voltage graph where a transistor can be used as an amplifier is?

- (1) active region
- (2) cut-off region
- (3) saturation region
- (4) passive region

Correct Answer: (1) active region

Solution:

Step 1: Understanding Transistor Operating Regions

A bipolar junction transistor (BJT) operates in three main regions:

- Cut-off Region: Both junctions are reverse biased, and the transistor is OFF (no conduction).
- Saturation Region: Both junctions are forward biased, and the transistor is fully ON (used in switching applications).
- Active Region: The base-emitter junction is forward biased, and the base-collector junction is reverse biased. In this region, the transistor functions as an amplifier.

Step 2: Why the Active Region is Used for Amplification

In the active region:

- A small change in the input base current causes a large change in the output collector current.
- The transistor operates linearly, making it suitable for amplification.

Step 3: Why Other Options Are Incorrect

- Cut-off Region (Option 2): Incorrect, as the transistor is OFF and does not conduct.
- Saturation Region (Option 3): Incorrect, as the transistor is fully ON and cannot amplify

signals.

- Passive Region (Option 4): Incorrect, as there is no such standard region in transistor operation.

Thus, the correct region where a transistor can be used as an amplifier is the active region.

Quick Tip

For a transistor to function as an amplifier, it must be in the active region, where the base-emitter junction is forward biased and the base-collector junction is reverse biased.

120. For an amplitude modulated wave, the maximum and minimum amplitudes are found to be 10 V and 2 V respectively. Then the modulation index is?

- (1) $\frac{3}{4}$
- (2) $\frac{1}{5}$
- (3) $\frac{1}{3}$
- (4) $\frac{2}{3}$

Correct Answer: (4) $\frac{2}{3}$

Solution:

Step 1: Understanding the Modulation Index

The modulation index (m) in amplitude modulation (AM) is given by:

$$m = \frac{A_{\max} - A_{\min}}{A_{\max} + A_{\min}}$$

where: - $A_{\max}$ is the maximum amplitude, - $A_{\min}$ is the minimum amplitude.

Step 2: Substituting Given Values

Given:

$$A_{\max} = 10V, \quad A_{\min} = 2V$$

$$m = \frac{10 - 2}{10 + 2}$$

$$= \frac{8}{12}$$

$$= \frac{2}{3}$$

Step 3: Verify the Correct Answer

Thus, the modulation index is $\frac{2}{3}$, which corresponds to Option (4).

Quick Tip

The modulation index in AM is calculated as $m = \frac{A_{\max} - A_{\min}}{A_{\max} + A_{\min}}$. A modulation index between 0 and 1 indicates proper amplitude modulation.

Chemistry

121. The wavelength of an electron is 10^3 nm. What is its momentum in kg m s^{-1} ?

($h = 6.625 \times 10^{-34}$ Js)

(1) 6.625×10^{-31}

(2) 6.625×10^{-37}

(3) 6.625×10^{-28}

(4) 6.625×10^{-34}

Correct Answer: (3) 6.625×10^{-28}

Solution:

Step 1: Use de Broglie's Equation

According to de Broglie's hypothesis, the momentum of a particle is given by:

$$p = \frac{h}{\lambda}$$

where: - $h = 6.625 \times 10^{-34}$ Js (Planck's constant), - $\lambda = 10^3$ nm = 10^{-6} m.

Step 2: Substitute the Given Values

$$p = \frac{6.625 \times 10^{-34}}{10^{-6}}$$

$$= 6.625 \times 10^{-28} \text{ kg m s}^{-1}$$

Step 3: Verify the Correct Answer

Thus, the momentum of the electron is $6.625 \times 10^{-28} \text{ kg m s}^{-1}$, which corresponds to Option (3).

Quick Tip

The de Broglie wavelength formula $p = \frac{h}{\lambda}$ is used to calculate the momentum of a particle. Ensure that the wavelength is converted into meters before substitution.

122. Two statements are given below:

Statement I: In H atom, the energy of 2s and 2p orbitals is the same.

Statement II: In He atom, the energy of 2s and 2p orbitals is the same.

- (1) Both statements I and II are correct
- (2) Both statements I and II are not correct
- (3) Statement I is correct but statement II is not correct
- (4) Statement I is not correct but statement II is correct

Correct Answer: (3) Statement I is correct but statement II is not correct

Solution:

Step 1: Energy Levels in a Hydrogen Atom

For a hydrogen atom (H), the energy of orbitals depends only on the principal quantum number (n) and not on the azimuthal quantum number (l). This means:

$$E_{2s} = E_{2p}$$

Thus, in a hydrogen atom, the energy of the 2s and 2p orbitals is the same, making Statement I correct.

Step 2: Energy Levels in a Helium Atom

For a helium atom (He), there is electron-electron interaction in addition to the nuclear attraction. Due to this, the energy of orbitals with the same principal quantum number (n) but different azimuthal quantum numbers (l) differs:

$$E_{2s} \neq E_{2p}$$

Thus, in a helium atom, the energy of the 2s and 2p orbitals is not the same, making Statement II incorrect.

Step 3: Verify the Correct Answer

Since Statement I is correct and Statement II is incorrect, the correct answer is Option (3).

Quick Tip

In single-electron atoms (like hydrogen), the energy of orbitals depends only on the principal quantum number (n). In multi-electron atoms (like helium), electron-electron interactions cause energy splitting among orbitals with the same n but different l .

123. The set containing the elements with positive electron gain enthalpies is?

- (1) S, Se, Te
- (2) Kr, Xe, Rn
- (3) Cl, Br, I
- (4) K, Rb, Cs

Correct Answer: (2) Kr, Xe, Rn

Solution:

Step 1: Understanding Electron Gain Enthalpy

Electron gain enthalpy (ΔH_{eg}) is the energy change when an atom gains an electron. It can be:

- **Negative** (exothermic): When energy is released, meaning the atom strongly attracts electrons (e.g., halogens).

- **Positive** (endothermic): When energy must be supplied to add an electron, meaning the atom resists gaining electrons (e.g., noble gases).

Step 2: Identifying Elements with Positive Electron Gain Enthalpy

- Option (1): S, Se, Te — Incorrect. These elements belong to group 16 (oxygen family) and generally have negative electron gain enthalpy.

- Option (2): Kr, Xe, Rn — Correct. These noble gases have completely filled electronic configurations, making electron addition unfavorable, resulting in a positive electron gain enthalpy.

- Option (3): Cl, Br, I — Incorrect. These are halogens with high electron affinity and negative electron gain enthalpy.

- Option (4): K, Rb, Cs — Incorrect. These alkali metals have low electron affinity but still have negative electron gain enthalpy.

Step 3: Verify the Correct Answer

Since noble gases resist electron gain due to their stable configuration, the set with positive electron gain enthalpy is Kr, Xe, Rn (Option 2).

Quick Tip

Noble gases have positive electron gain enthalpy because their full valence shells make adding an extra electron energetically unfavorable.

124. Assertion (A): The ionic radii of Na^+ and F^- are the same.

Reason (R): Both Na^+ and F^- are isoelectronic species.

(1) (A) and (R) are correct. (R) is the correct explanation of (A)

(2) (A) and (R) are correct, but (R) is not the correct explanation of (A)

(3) (A) is correct but (R) is not correct

(4) (A) is not correct but (R) is correct

Correct Answer: (4) (A) is not correct but (R) is correct

Solution:

Step 1: Understanding Isoelectronic Species

Isoelectronic species have the same number of electrons but different nuclear charges. Both Na^+ (11 protons, 10 electrons) and F^- (9 protons, 10 electrons) are isoelectronic.

Thus, Reason (R) is correct.

Step 2: Comparing Ionic Radii of Na^+ and F^-

- Na^+ is a cation formed by losing one electron, reducing electron-electron repulsion and making it smaller than its parent atom.
- F^- is an anion formed by gaining one electron, increasing electron-electron repulsion and making it larger than its parent atom.

Since Na^+ has a smaller radius than F^- , the assertion that their radii are the same is incorrect.

Step 3: Verify the Correct Answer

Since (A) is incorrect but (R) is correct, the correct answer is Option (4).

Quick Tip

Isoelectronic species have the same number of electrons but different sizes due to varying nuclear charges. Cations (Na^+) are smaller than their neutral atoms, while anions (F^-) are larger.

125. The number of lone pairs of electrons on the central atom of ClF_3 , NF_3 , SF_4 , XeF_4 respectively are?

- (1) 0, 1, 0, 2
- (2) 2, 1, 0, 0
- (3) 2, 1, 1, 2
- (4) 2, 1, 1, 0

Correct Answer: (3) 2, 1, 1, 2

Solution:

To determine the number of lone pairs on the central atom in each molecule, we use the Valence Shell Electron Pair Repulsion (VSEPR) Theory.

Step 1: Lone Pairs in ClF_3

- Chlorine (Cl) has 7 valence electrons.
- Fluorine atoms use 3 bonding pairs, leaving 2 lone pairs.
- Molecular geometry: T-shaped.

Thus, the lone pairs on $ClF_3 = 2$.

Step 2: Lone Pairs in NF_3

- Nitrogen (N) has 5 valence electrons.
- Three fluorine atoms form 3 bonding pairs, leaving 1 lone pair.
- Molecular geometry: Trigonal pyramidal.

Thus, the lone pairs on $NF_3 = 1$.

Step 3: Lone Pairs in SF_4

- Sulfur (S) has 6 valence electrons.
- Four fluorine atoms form 4 bonding pairs, leaving 1 lone pair.
- Molecular geometry: Seesaw.

Thus, the lone pairs on $SF_4 = 1$.

Step 4: Lone Pairs in XeF_4

- Xenon (Xe) has 8 valence electrons.
- Four fluorine atoms form 4 bonding pairs, leaving 2 lone pairs.
- Molecular geometry: Square planar.

Thus, the lone pairs on $XeF_4 = 2$.

Step 5: Verify the Correct Answer

From our calculations, the number of lone pairs on the central atoms is 2, 1, 1, 2, which matches Option (3).

Quick Tip

To determine lone pairs on a central atom, use the VSEPR theory and subtract the bonding pairs from the total valence electrons. The remaining pairs are lone pairs.

126. The hybridisation of the central atom of BF_3 , $SnCl_2$, $HgCl_2$, respectively is?

- (1) sp^2 , sp^2 , sp
- (2) sp^3 , sp^2 , sp^2

(3) sp^3 , sp , sp^2

(4) sp^3 , sp , sp

Correct Answer: (1) sp^2 , sp^2 , sp

Solution:

The hybridization of a molecule can be determined using the steric number, which is given by:

$$\text{Steric Number} = \text{Number of bonded atoms} + \text{Number of lone pairs}$$

Step 1: Hybridization of BF_3

- Boron (B) has 3 valence electrons and forms 3 sigma bonds with fluorine atoms.
- No lone pairs on boron.
- Steric number = 3, which corresponds to sp^2 hybridization.
- Molecular geometry: Trigonal planar.

Thus, the hybridization of BF_3 is sp^2 .

Step 2: Hybridization of $SnCl_2$

- Tin (Sn) has 4 valence electrons and forms 2 sigma bonds with chlorine atoms.
- It has one lone pair.
- Steric number = 3, which corresponds to sp^2 hybridization.
- Molecular geometry: Bent (V-shape).

Thus, the hybridization of $SnCl_2$ is sp^2 .

Step 3: Hybridization of $HgCl_2$

- Mercury (Hg) has 2 valence electrons and forms 2 sigma bonds with chlorine atoms.
- No lone pairs on mercury in this case.
- Steric number = 2, which corresponds to sp hybridization.
- Molecular geometry: Linear.

Thus, the hybridization of $HgCl_2$ is sp .

Step 4: Verify the Correct Answer

From our calculations, the hybridizations are sp^2 , sp^2 , sp , which matches Option (1).

Quick Tip

The hybridization of an atom can be determined using the steric number formula:

$$\text{Steric Number} = \text{Number of bonded atoms} + \text{Number of lone pairs}$$

A steric number of 2 corresponds to sp , 3 to sp^2 , and 4 to sp^3 .

127. The variation of volume of an ideal gas with its number of moles (n) is obtained as a graph at 300 K and 1 atm pressure. What is the slope of the graph?

- (1) 24.6 L
- (2) 24.6 L mol⁻¹
- (3) $\frac{1}{24.6}$ L
- (4) $\frac{1}{24.6}$ L⁻¹ mol

Correct Answer: (2) 24.6 L mol⁻¹

Solution:

Step 1: Use the Ideal Gas Equation

The ideal gas equation is:

$$PV = nRT$$

where: - P is the pressure (1 atm), - V is the volume, - n is the number of moles, - R is the universal gas constant (0.0821 L atm mol⁻¹ K⁻¹), - T is the temperature (300 K).

Step 2: Express Volume as a Function of n

Rearranging the equation:

$$V = \frac{nRT}{P}$$

Since $R = 0.0821$, $T = 300$ K, and $P = 1$ atm:

$$V = \frac{(n)(0.0821)(300)}{1}$$

$$V = 24.6n$$

Step 3: Identify the Slope

The equation is in the form:

$$V = mn$$

where m (the slope) is 24.6 L mol^{-1} .

Step 4: Verify the Correct Answer

Thus, the slope of the graph is 24.6 L mol^{-1} , which matches Option (2).

Quick Tip

For an ideal gas at STP (1 atm, 273 K), the molar volume is 22.4 L. At 300 K, it increases to approximately 24.6 L per mole. The slope of a volume vs. moles graph is given by $\frac{RT}{P}$.

128. Observe the following reaction:

In this reaction:

- (1) Cl is oxidized and O is reduced
- (2) Cl is reduced and O is oxidized
- (3) K is oxidized and O is reduced
- (4) K is reduced and Cl is also reduced

Correct Answer: (2) Cl is reduced and O is oxidized

Solution:

Step 1: Assign Oxidation Numbers

In potassium chlorate ($KClO_3$): - Potassium (K) has an oxidation state of +1. - Oxygen (O) in oxoanions typically has an oxidation state of -2. - Let the oxidation state of chlorine (Cl) be x .

Using the sum rule for a neutral compound:

$$(+1) + x + 3(-2) = 0$$

$$x - 6 + 1 = 0$$

$$x = +5$$

Thus, in $KClO_3$, Cl has an oxidation state of +5.

In potassium chloride (KCl): - K is still +1. - Cl must be -1 to balance the charge.

Thus, the oxidation state of Cl changes from +5 in $KClO_3$ to -1 in KCl , meaning Cl is **reduced**.

Step 2: Identify Oxidation of Oxygen

In $KClO_3$, oxygen is in the -2 oxidation state. In O_2 gas, oxygen exists in its elemental form, which has an oxidation state of 0.

Since oxygen's oxidation state increases from -2 to 0, oxygen is oxidized.

Step 3: Verify the Correct Answer

- Chlorine is reduced (from +5 to -1). - Oxygen is oxidized (from -2 to 0).

Thus, the correct answer is Option (2): Cl is reduced and O is oxidized.

Quick Tip

Oxidation refers to an increase in oxidation state, while reduction refers to a decrease. In this reaction, oxygen is oxidized, and chlorine is reduced, demonstrating a classic redox process.

129. The $\Delta_f H^\theta$ of $AO_3(s)$, $BO_2(s)$, and $ABO_3(s)$ is -635, x , and -1210 kJ mol⁻¹ respectively. The reaction:

$ABO_3(s) \rightarrow AO(s) + BO_2(g)$ Has an enthalpy change of $\Delta_r H^\theta = 175 \text{ kJ mol}^{-1}$. What is the value of x (in kJ mol^{-1})?

(1) -750

(2) $+400$

(3) -400

(4) $+750$

Correct Answer: (3) -400

Solution:

Step 1: Understanding the Given Data

We are given the standard enthalpies of formation ($\Delta_f H^\theta$):

$$\Delta_f H^\theta(AO_3) = -635 \text{ kJ mol}^{-1}$$

$$\Delta_f H^\theta(ABO_3) = -1210 \text{ kJ mol}^{-1}$$

$$\Delta_r H^\theta = 175 \text{ kJ mol}^{-1}$$

We need to determine the enthalpy of formation of BO_2 , denoted as x .

Step 2: Applying Hess's Law

From the reaction:

Using the enthalpy change equation:

$$\Delta_r H^\theta = \sum \Delta_f H^\theta(\text{products}) - \sum \Delta_f H^\theta(\text{reactants})$$

$$175 = (-635 + x) - (-1210)$$

Step 3: Solving for x

$$175 = -635 + x + 1210$$

$$x = 175 - 1210 + 635$$

$$x = -400 \text{ kJ mol}^{-1}$$

Step 4: Verify the Correct Answer

Thus, the value of x is -400 kJ mol^{-1} , which matches Option (3).

Quick Tip

Hess's Law states that the enthalpy change of a reaction is the sum of the enthalpy changes of its components. Use the equation:

$$\Delta_r H^\theta = \sum \Delta_f H^\theta(\text{products}) - \sum \Delta_f H^\theta(\text{reactants})$$

to Solving enthalpy-related problems.

130. At 27°C, 100 mL of 0.5 M HCl is mixed with 100 mL of 0.4 M NaOH solution. To this resultant solution, 800 mL of distilled water is added. What is the pH of the final solution?

- (1) 12.0
- (2) 2.0
- (3) 1.3
- (4) 1.0

Correct Answer: (2) 2.0

Solution:

Step 1: Calculate the Moles of HCl and NaOH

$$\text{Moles of HCl} = M \times V = (0.5 \text{ M}) \times (0.1 \text{ L}) = 0.05 \text{ moles}$$

$$\text{Moles of NaOH} = M \times V = (0.4 \text{ M}) \times (0.1 \text{ L}) = 0.04 \text{ moles}$$

Step 2: Determine the Excess Acid or Base

Since HCl and NaOH react in a 1:1 ratio:

$$\text{Remaining HCl} = 0.05 - 0.04 = 0.01 \text{ moles}$$

Step 3: Calculate the Final Concentration of H^+

Total volume after mixing:

$$100 \text{ mL} + 100 \text{ mL} + 800 \text{ mL} = 1000 \text{ mL} = 1 \text{ L}$$

$$[H^+] = \frac{\text{Remaining moles of HCl}}{\text{Total volume in L}} = \frac{0.01}{1} = 0.01 \text{ M}$$

Step 4: Calculate the pH

$$\text{pH} = -\log[H^+]$$

$$\text{pH} = -\log(0.01) = 2.0$$

Step 5: Verify the Correct Answer

Thus, the final pH of the solution is 2.0, which matches Option (2).

Quick Tip

When a strong acid (HCl) and a strong base (NaOH) are mixed, Solve for the limiting reagent and determine the excess moles remaining. Then, use the total volume to calculate the final concentration and determine the pH.

131. The proper Statements of storing H_2O_2 are:

- (1) Placing in wax lined plastic bottle and kept in dark
- (2) Placing in wax lined plastic bottle and exposed to light
- (3) Placing in wax lined plastic bottle containing traces of base

(4) Placing in metal vessel and exposed to light

Correct Answer: (1) Placing in wax lined plastic bottle and kept in dark

Solution:

Step 1: Understanding the storage Statements for H_2O_2

Hydrogen peroxide (H_2O_2) is a highly reactive and unstable compound. It decomposes easily when exposed to light, heat, or contaminants. The decomposition reaction is as follows:

This reaction is catalyzed by light, heat, and impurities such as dust or metal ions.

Step 2: Simplifying the given options

- Option (1): Storing H_2O_2 in a wax-lined plastic bottle and keeping it in the dark is the correct approach, as it prevents light exposure and avoids contamination from metal ions.
- Option (2): Exposing H_2O_2 to light accelerates its decomposition, making this an incorrect choice.
- Option (3): Adding a base catalyzes the decomposition of H_2O_2 , making it an incorrect storage Statement.
- Option (4): Storing in a metal vessel leads to contamination with metal ions, which further accelerates decomposition.

Thus, the correct answer is **Option (1)**.

Quick Tip

Hydrogen peroxide should always be stored in a cool, dark place, preferably in a plastic or glass container with a stabilizer. Avoid exposure to light and metals to prevent rapid decomposition.

132. The standard electrode potentials $E^\circ(V)$ for Li^+/Li , Na^+/Na respectively are:

- (1) $-3.04, -2.714$
- (2) $-2.714, -3.04$
- (3) $-3.04, -3.04$

(4) $-2.714, -2.714$

Correct Answer: (1) $-3.04, -2.714$

Solution:

Step 1: Understanding Standard Electrode Potential

The standard electrode potential (E°) of an element is a measure of the tendency of the element to gain or lose electrons in an electrochemical reaction. It is given in volts (V) and is measured under standard conditions.

Step 2: Standard Electrode Potentials for Lithium and Sodium

- For lithium, the standard reduction potential is:

- For sodium, the standard reduction potential is:

Step 3: Simplifying the Given Options

- Option (1): $-3.04, -2.714$ – Correct as per standard data.
- Option (2): $-2.714, -3.04$ – Incorrect as the values are reversed.
- Option (3): $-3.04, -3.04$ – Incorrect as the value for sodium is wrong.
- Option (4): $-2.714, -2.714$ – Incorrect as the value for lithium is wrong.

Thus, the correct answer is **Option (1)**.

Quick Tip

The more negative the standard electrode potential (E°), the stronger the reducing agent. Lithium has a more negative potential than sodium, making it a stronger reducing agent.

133. The alloy formed by beryllium with 'X' is used in the preparation of high-strength springs. 'X' is:

- (1) Al
- (2) Zn

(3) Cu

(4) Cr

Correct Answer: (3) Cu

Solution:

Step 1: Understanding Beryllium Alloys

Beryllium forms several alloys, but one of the most notable is beryllium copper ($Be - Cu$). This alloy is widely used due to its high strength, good electrical conductivity, and non-magnetic properties.

Step 2: Properties and Applications of Beryllium Copper

- Beryllium copper ($Be - Cu$) is a non-sparking, non-magnetic alloy with excellent strength and corrosion resistance. - It is used in the manufacture of high-strength springs, precision instruments, and aerospace components. - The combination of beryllium with copper enhances mechanical strength while maintaining electrical conductivity.

Step 3: Simplifying the Given Options

- Option (1) Al: Beryllium-aluminum alloys exist but are not commonly used for high-strength springs.
- Option (2) Zn: Zinc alloys do not typically involve beryllium in significant amounts for mechanical applications.
- Option (3) Cu: Correct, as beryllium copper is used in high-strength springs.
- Option (4) Cr: Chromium forms strong alloys but is not the primary metal used with beryllium for this application.

Thus, the correct answer is **Option (3)**.

Quick Tip

Beryllium copper ($Be - Cu$) is a unique alloy known for its high strength, electrical conductivity, and corrosion resistance. It is widely used in precision instruments, aerospace applications, and non-sparking tools.

134. What are X and Y respectively in the following reactions?

(1) $BH_3, 2CO; NaBO_2$

(2) $BH_3, CO; NaBH_4$

(3) $BH_3, CO; NaBO_2$

(4) $BH_3, CO; Na_2B_4O_7$

Correct Answer: (2) $BH_3, CO; NaBH_4$

Solution:

Step 1: Understanding the Reaction Sequence

The given reaction sequence involves a series of transformations starting from X and leading to Y . Let's analyze the stepwise reactions:

1. The first reaction suggests that X reacts with carbon monoxide (CO) to form diborane (B_2H_6). This indicates that X is borane (BH_3), which is a well-known precursor to diborane formation.
2. Diborane (B_2H_6) then reacts with sodium hydride (NaH), leading to the formation of sodium borohydride ($NaBH_4$).
3. The presence of diethyl ether ($(C_2H_5)_2O$) as a Solvingnt helps stabilize the final product.

Step 2: Simplifying the Given Options

- Option (1): Incorrect as it suggests $X = BH_3, 2CO$, which is not required for diborane formation.
- Option (2): Correct as it correctly identifies $X = BH_3$ and $Y = NaBH_4$.
- Option (3): Incorrect as it wrongly identifies Y as sodium metaborate ($NaBO_2$).
- Option (4): Incorrect as it suggests $Y = Na_2B_4O_7$, which does not match the reaction sequence.

Thus, the correct answer is **Option (2)**.

Quick Tip

Borane (BH_3) is a key reagent in boron chemistry and forms diborane (B_2H_6) upon dimerization. Sodium borohydride ($NaBH_4$) is commonly used as a reducing agent in organic synthesis.

135. Which of the following statements are correct?

- (i) CCl_4 undergoes hydrolysis easily.
 - (ii) Diamond has directional covalent bonds.
 - (iii) Fullerene is the thermodynamically most stable allotrope of carbon.
 - (iv) Glass is a man-made silicate.
- (1) *i, iii* only
 - (2) *ii, iv* only
 - (3) *ii, iii, iv* only
 - (4) *i, ii* only

Correct Answer: (2) *ii, iv* only

Solution:

Step 1: Analyzing Each Statement

1. Statement (i): Incorrect. Carbon tetrachloride (CCl_4) does not undergo hydrolysis easily because it lacks vacant *d*-orbitals, making it resistant to nucleophilic attack by water molecules.
2. Statement (ii): Correct. Diamond has a tetrahedral structure where each carbon atom is bonded to four other carbon atoms through strong directional covalent bonds, giving it high hardness and rigidity.
3. Statement (iii): Incorrect. Graphite, not fullerene, is the most thermodynamically stable allotrope of carbon due to its lower energy configuration.
4. Statement (iv): Correct. Glass is an amorphous, man-made silicate composed mainly of silica (SiO_2), which is fused with other compounds like sodium oxide and calcium oxide.

Step 2: Simplifying the Given Options

- Option (1): Incorrect, as statement (i) is incorrect.
- Option (2): Correct, as statements (ii) and (iv) are the only correct ones.
- Option (3): Incorrect, as statement (iii) is incorrect.
- Option (4): Incorrect, as statement (i) is incorrect.

Thus, the correct answer is **Option (2)**.

Quick Tip

Diamond has directional covalent bonds, making it extremely hard. Glass is a synthetic silicate material, while graphite is the most stable allotrope of carbon, not fullerene.

136. Which of the following industries generate non-biodegradable wastes?

- (1) Cotton mills
- (2) Paper mills
- (3) Thermal power plants
- (4) Textile factories

Correct Answer: (3) Thermal power plants

Solution:

Step 1: Understanding Non-Biodegradable Waste

Non-biodegradable waste refers to materials that do not decompose naturally and persist in the environment for a long time, causing pollution. These include plastics, heavy metals, industrial chemicals, and fly ash.

Step 2: Analyzing the Given Industries

1. Cotton mills: Incorrect. Cotton mills primarily generate biodegradable waste, such as natural fiber residues.
2. Paper mills: Incorrect. Paper waste is mostly biodegradable and recyclable.
3. Thermal power plants: Correct. These plants generate large amounts of non-biodegradable waste such as fly ash, bottom ash, and heavy metal residues, which contribute to environmental pollution.
4. Textile factories: Incorrect. Textile waste can include biodegradable materials like natural fibers, though synthetic fibers may persist longer.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as cotton waste is biodegradable.
- Option (2): Incorrect, as paper is mostly biodegradable.
- Option (3): Correct, as thermal power plants generate non-biodegradable industrial waste.

- Option (4): Incorrect, as textile waste varies, but most of it is biodegradable.

Thus, the correct answer is **Option (3)**.

Quick Tip

Thermal power plants produce non-biodegradable waste like fly ash and heavy metals. These pollutants can persist in the environment and require proper disposal methods.

137. Possible number of isomers including stereoisomers for an organic compound with the molecular formula C_4H_9Br is:

- (1) 3
- (2) 4
- (3) 5
- (4) 2

Correct Answer: (3) 5

Solution:

Step 1: Understanding Isomerism

Isomers are compounds with the same molecular formula but different structural arrangements or spatial orientations. The molecular formula given is C_4H_9Br , which corresponds to butyl bromide isomers.

Step 2: Identifying the Isomers

The possible structural and stereoisomers for C_4H_9Br are:

1. n-Butyl bromide ($CH_3CH_2CH_2CH_2Br$) - Straight-chain structure.
2. Isobutyl bromide ($(CH_3)_2CHCH_2Br$) - Branched structure.
3. Sec-butyl bromide ($CH_3CHBrCH_2CH_3$) - Branched with a secondary carbon.
4. Tert-butyl bromide ($(CH_3)_3CBr$) - Branched with a tertiary carbon.
5. Sec-butyl bromide has a chiral center, leading to two enantiomers, contributing to stereoisomerism.

Step 3: Simplifying the Given Options

- Option (1) 3: Incorrect, as it does not account for all possible isomers.
- Option (2) 4: Incorrect, as it excludes stereoisomers.
- Option (3) 5: Correct, as it includes all structural and stereoisomers.
- Option (4) 2: Incorrect, as more isomers exist.

Thus, the correct answer is **Option (3)**.

Quick Tip

When counting isomers, consider both structural and stereoisomers. Compounds with chiral centers contribute to additional enantiomers, increasing the total count.

138. The alkane which is next to methane in the homologous series can be prepared from which of the following reactions?

- I $2\text{CH}_3\text{Br} \xrightarrow[\text{dry ether}]{\text{Na}} \rightarrow$
- II $\text{CH}_3\text{COOH} \xrightarrow[\text{CaO}, \Delta]{\text{NaOH}} \rightarrow$
- III $\text{CH}_3\text{CH}=\text{CH}_2 \xrightarrow{\text{H}_2/\text{Pt}} \rightarrow$
- IV $\text{CH}_3\text{CH}_2\text{Br} \xrightarrow[\text{H}^+]{\text{Zn}} \rightarrow$

- (1) I, IV only
- (2) II, III only
- (3) I, III only
- (4) II, IV only

Correct Answer: (1) I, IV only

Solution:

Step 1: Understanding the homologous series

The homologous series of alkanes consists of compounds differing by a $-\text{CH}_2-$ group. The alkane next to methane is ethane (C_2H_6).

Step 2: Simplifying the given reactions

1. Reaction I: Wurtz Reaction

This reaction successfully forms ethane, making it a correct method.

2. Reaction II: Decarboxylation of Carboxylic Acids

This reaction produces methane, not ethane, so it is incorrect.

3. Reaction III: Hydrogenation of Ethene

This reaction forms ethane, but it is not the best preparative method for homologous series alkane synthesis.

4. Reaction IV: Reduction of Alkyl Halides

This reaction also produces ethane, making it a valid method.

Step 3: Simplifying the Given Options

- Option (1): Correct, as I (Wurtz reaction) and IV (alkyl halide reduction) are the valid methods.
- Option (2): Incorrect, as II produces methane instead of ethane.
- Option (3): Incorrect, as I is correct but III is not a conventional method for preparing alkanes in a homologous series.
- Option (4): Incorrect, as II does not yield ethane.

Thus, the correct answer is **Option (1)**.

Quick Tip

The Wurtz reaction is a reliable method for synthesizing alkanes by coupling alkyl halides with sodium metal in dry ether. The reduction of alkyl halides using zinc and acid also effectively produces alkanes.

139. At high pressure and regulated supply of air, methane is heated with catalyst 'X' to give methanol and with catalyst 'Y' to give methanal. X and Y respectively are:

- (1) Mo_2O_3, Cu
- (2) Cu, Mo_2O_3
- (3) $V_2O_5, KMnO_4$
- (4) $KMnO_4, Cr_2O_3$

Correct Answer: (2) Cu, Mo_2O_3

Solution:

Step 1: Understanding the Oxidation of Methane

Methane (CH_4) can be oxidized under controlled conditions to form methanol (CH_3OH) and methanal ($HCHO$). The choice of catalyst determines the specific oxidation product.

Step 2: Identifying the Catalysts

1. Formation of Methanol (CH_3OH):

- Methane is converted to methanol using copper (Cu) as a catalyst under high pressure.

2. Formation of Methanal ($HCHO$):

- Methane is converted to methanal using molybdenum oxide (Mo_2O_3) as a catalyst.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as it swaps the catalysts.
- Option (2): Correct, as Cu is used for methanol and Mo_2O_3 for methanal.
- Option (3): Incorrect, as V_2O_5 and $KMnO_4$ are not the catalysts used in this reaction.
- Option (4): Incorrect, as $KMnO_4$ and Cr_2O_3 are not the correct catalysts.

Thus, the correct answer is **Option (2)**.

Quick Tip

In oxidation reactions of methane, copper (Cu) is used for converting methane to methanol, while molybdenum oxide (Mo_2O_3) is used for converting methane to methanal.

140. What is 'Y' in the following set of reactions?

Correct Answer: (2) 

Solution:

Step 1: Understanding the Reaction Sequence

1. Step 1: Acid-Catalyzed Hydration of Alkene

- The given compound C_4H_8 is an alkene.
- In the presence of sulfuric acid (H_2SO_4) and water, Markovnikov's rule applies, leading to the formation of a more substituted alcohol.

2. Step 2: Ozonolysis Reaction

- The alcohol undergoes ozonolysis (O_3 , Zn/H_2O), which cleaves the double bond and forms aldehydes or ketones depending on the structure of the starting material.

Step 2: Identifying 'Y'

- The given reactant is butene (C_4H_8).
- Hydration leads to the formation of butan-2-ol as the intermediate product.
- Ozonolysis of butan-2-ol results in acetone (CH_3COCH_3) and formaldehyde ($HCHO$).

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as it does not match the expected ozonolysis products.
- Option (2): Correct, as it represents acetone and formaldehyde.

- Option (3): Incorrect, as it does not correspond to the reaction mechanism.
- Option (4): Incorrect, as it represents a different structural outcome.

Thus, the correct answer is **Option (2)**.

Quick Tip

Ozonolysis of alkenes results in the cleavage of the double bond, producing aldehydes or ketones. When dealing with hydration reactions, always apply Markovnikov's rule to determine the major product.

141. The molecular formula of a crystal is AB_2O_4 . Oxygen atoms form a close-packed lattice. Atoms of A occupy $x\%$ of tetrahedral voids and atoms of B occupy $y\%$ of octahedral voids. x and y are respectively:

- (1) 12.5%, 50%
- (2) 50%, 12.5%
- (3) 33.3%, 66.6%
- (4) 66.6%, 33.3%

Correct Answer: (1) 12.5%, 50%

Solution:

Step 1: Understanding the Crystal Structure

The given compound is AB_2O_4 , which follows the spinel structure. In such structures:

- Oxygen atoms form a face-centered cubic (FCC) close-packed lattice.
- The tetrahedral voids and octahedral voids are partially occupied by A and B atoms, respectively.

Step 2: Analyzing the Void Occupation

1. Tetrahedral Voids:

- In an FCC lattice of oxygen, the number of tetrahedral voids is twice the number of oxygen atoms.
- A fraction of these voids is occupied by A atoms.

2. Octahedral Voids:

- The number of octahedral voids is equal to the number of oxygen atoms.
- A fraction of these voids is occupied by B atoms.

Step 3: Calculating x and y

- Total oxygen atoms = 4 per formula unit.
- Total tetrahedral voids = $2 \times 4 = 8$.
- Total octahedral voids = 4.

For A atoms:

- The formula tells us that 1 atom of A is present.
- A atoms occupy tetrahedral voids.
- The fraction occupied by A is $\frac{1}{8} = 12.5\%$.

For B atoms:

- The formula tells us that 2 atoms of B are present.
- B atoms occupy octahedral voids.
- The fraction occupied by B is $\frac{2}{4} = 50\%$.

Step 4: Simplifying the Given Options

- Option (1): Correct, as $x = 12.5\%$, $y = 50\%$.
- Option (2): Incorrect, as it reverses the values.
- Option (3): Incorrect, as it does not match calculated values.
- Option (4): Incorrect, as the values are swapped incorrectly.

Thus, the correct answer is **Option (1)**.

Quick Tip

In a spinel structure (AB_2O_4), A atoms typically occupy tetrahedral voids while B atoms occupy octahedral voids. The percentage occupation is determined based on the number of available voids.

142. At T(K), 0.1 moles of a non-volatile solute was dissolved in 0.9 moles of a volatile solvent. The vapour pressure of pure solvent is 0.9 bar. What is the vapour pressure (in bar) of the solution?

(1) 0.89

(2) 0.81

(3) 0.79

(4) 0.71

Correct Answer: (2) 0.81

Solution:

Step 1: Understanding Raoult's Law

Raoult's Law states that the vapour pressure of a solution (P_{solution}) is given by:

$$P_{\text{solution}} = P_{\text{Solvingnt}}^0 \times X_{\text{Solvingnt}}$$

where: - $P_{\text{Solvingnt}}^0$ is the vapour pressure of the pure Solvingnt. - $X_{\text{Solvingnt}}$ is the mole fraction of the Solvingnt.

Step 2: Calculating the Mole Fraction of the Solvingnt

$$X_{\text{Solvingnt}} = \frac{\text{moles of Solvingnt}}{\text{total moles in solution}}$$

Given: - Moles of solute = 0.1 - Moles of Solvingnt = 0.9 - Vapour pressure of pure Solvingnt = 0.9 bar

Total moles in the solution:

$$0.9 + 0.1 = 1.0$$

Mole fraction of the Solvingnt:

$$X_{\text{Solvingnt}} = \frac{0.9}{1.0} = 0.9$$

Step 3: Calculating the Vapour Pressure of the Solution

Applying Raoult's Law:

$$P_{\text{solution}} = 0.9 \times 0.9 = 0.81 \text{ bar}$$

Step 4: Simplifying the Given Options

- Option (1): Incorrect, as 0.89 is too high.
- Option (2): Correct, as calculated $P_{\text{solution}} = 0.81 \text{ bar}$.

- Option (3): Incorrect, as 0.79 is not accurate.
- Option (4): Incorrect, as 0.71 is too low.

Thus, the correct answer is **Option (2)**.

Quick Tip

To Solve for the vapour pressure of a solution, use Raoult's Law: $P_{\text{solution}} = P_{\text{Solvingnt}}^0 \times X_{\text{Solvingnt}}$. Always check the mole fraction carefully for accuracy.

143. Two statements are given below:

Statement I: Molten NaCl is electrolysed using Pt electrodes. Cl_2 is liberated at the anode.

Statement II: Aqueous $CuSO_4$ is electrolysed using Pt electrodes. O_2 is liberated at the cathode.

The correct answer is:

- (1) Both statement I and II are correct
- (2) Both statement I and II are not correct
- (3) Statement I is correct but statement II is not correct
- (4) Statement I is not correct but statement II is correct

Correct Answer: (3) Statement I is correct but statement II is not correct

Solution:

Step 1: Understanding Electrolysis of Molten NaCl

- When molten sodium chloride ($NaCl$) is electrolysed using platinum electrodes, it undergoes the following reactions:

- At the cathode (-): $Na^+ + e^- \rightarrow Na$ (Sodium metal is deposited)
- At the anode (+): $2Cl^- \rightarrow Cl_2 + 2e^-$ (Chlorine gas is liberated)
- Therefore, Statement I is correct since Cl_2 is indeed liberated at the anode.

Step 2: Understanding Electrolysis of Aqueous $CuSO_4$

- When aqueous copper sulfate ($CuSO_4$) is electrolysed using platinum electrodes:
- At the cathode: $Cu^{2+} + 2e^- \rightarrow Cu$ (Copper is deposited)
- At the anode: $2H_2O \rightarrow O_2 + 4H^+ + 4e^-$ (Oxygen gas is liberated)

- However, the oxygen gas is liberated at the anode, not at the cathode, making Statement II incorrect.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, because Statement II is incorrect.
- Option (2): Incorrect, as Statement I is correct.
- Option (3): Correct, as Statement I is correct, and Statement II is incorrect.
- Option (4): Incorrect, as Statement I is correct.

Thus, the correct answer is **Option (3)**.

Quick Tip

During electrolysis of molten NaCl, chlorine gas is liberated at the anode. In aqueous CuSO₄ electrolysis with platinum electrodes, oxygen is released at the anode, not at the cathode.

144. For a first-order reaction, the graph between $\log \frac{a}{(a-x)}$ (on y-axis) and time (in min, on x-axis) gave a straight line passing through the origin. The slope is $2 \times 10^{-3} \text{ min}^{-1}$. What is the rate constant (in min^{-1})?

- (1) 2×10^{-3}
- (2) $\frac{2 \times 10^{-3}}{2.303}$
- (3) 4.606×10^{-3}
- (4) 0.5×10^{-5}

Correct Answer: (3) 4.606×10^{-3}

Solution:

Step 1: Understanding the First-Order Rate Equation

For a first-order reaction, the integrated rate law is:

$$\log \frac{a}{(a-x)} = kt$$

Comparing this with the equation of a straight line ($y = mx$), we see that:

$$\text{slope} = k \times \frac{2.303}{1}$$

Step 2: Calculating the Rate Constant k

Given:

$$\text{slope} = 2 \times 10^{-3} \text{ min}^{-1}$$

Using the relation:

$$k = \text{slope} \times 2.303$$

$$k = (2 \times 10^{-3}) \times 2.303$$

$$k = 4.606 \times 10^{-3} \text{ min}^{-1}$$

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as k is not directly equal to the slope.
- Option (2): Incorrect, as it divides by 2.303 instead of multiplying.
- Option (3): Correct, as $k = 4.606 \times 10^{-3} \text{ min}^{-1}$.
- Option (4): Incorrect, as the value is far too small.

Thus, the correct answer is **Option (3)**.

Quick Tip

For first-order reactions, the rate constant k is obtained from the slope of the plot $\log \frac{a}{(a-x)}$ vs. time using the formula: $k = \text{slope} \times 2.303$.

145. In Haber's process of manufacture of ammonia, the 'catalyst', the 'promoter', and 'poison for the catalyst' are respectively:

- (1) Fe, W, CO
- (2) Co, Mo, CO
- (3) Fe, Mo, CO_2

(4) Fe, Mo, CO

Correct Answer: (4) Fe, Mo, CO

Solution:

Step 1: Understanding the Haber Process

The Haber process is used for the industrial production of ammonia (NH_3) from nitrogen (N_2) and hydrogen (H_2) under high pressure and temperature. The reaction is:

Step 2: Identifying the Catalyst, Promoter, and Poison

- Catalyst: Iron (Fe) is used as the main catalyst to increase the rate of reaction.
- Promoter: Molybdenum (Mo) is added as a promoter to enhance the efficiency of iron as a catalyst.
- Poison for the Catalyst: Carbon monoxide (CO) acts as a poison for the iron catalyst by adsorbing on its active sites and deactivating it.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as tungsten (W) is not used in the Haber process.
 - Option (2): Incorrect, as cobalt (Co) is not the main catalyst.
 - Option (3): Incorrect, as CO_2 is not the primary catalyst poison.
 - Option (4): Correct, as the correct catalyst is Fe , the promoter is Mo , and the poison is CO .
- Thus, the correct answer is **Option (4)**.

Quick Tip

In the Haber process, iron (Fe) is used as the catalyst, molybdenum (Mo) as a promoter, and carbon monoxide (CO) acts as a catalyst poison, reducing efficiency by adsorbing on the catalyst surface.

146. Among the following, the calcination process is:

Correct Answer: (4)

Solution:

Step 1: Understanding Calcination

Calcination is the process of heating an ore in the absence or limited supply of air to remove volatile impurities such as water (H_2O), carbon dioxide (CO_2), or sulfur dioxide (SO_2). It is used primarily for carbonate and hydrated ores.

Step 2: Analyzing the Given Reactions

1. Reaction (1): Roasting Process

- This reaction involves heating a sulfide ore (Cu_2S) in the presence of oxygen (O_2), leading to the formation of oxide (Cu_2O) and the release of sulfur dioxide (SO_2).
- This is a roasting process, not calcination.

2. Reaction (2): Dissolution Reaction

- This reaction involves aluminum oxide (Al_2O_3) reacting with sodium hydroxide (NaOH) and water to form sodium aluminate.
- This is a leaching reaction, not calcination.

3. Reaction (3): Roasting Process

- This reaction involves heating a sulfide ore (CuFeS_2) in the presence of oxygen (O_2), forming copper sulfide (Cu_2S), iron sulfide (FeS), and sulfur dioxide (SO_2).
- Since it involves oxidation of sulfides, it is also a roasting process, not calcination.

4. Reaction (4): Calcination Process

- This reaction involves heating hydrated iron oxide ($\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$) to remove water (H_2O), leaving behind anhydrous iron oxide (Fe_2O_3).
- This matches the definition of calcination.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as it represents roasting.
- Option (2): Incorrect, as it represents a dissolution reaction.
- Option (3): Incorrect, as it represents roasting.
- Option (4): Correct, as it represents the calcination of hydrated iron oxide.

Thus, the correct answer is **Option (4)**.

Quick Tip

Calcination is used for removing volatile components like water and carbon dioxide from ores by heating in limited air. Roasting, on the other hand, involves heating sulfide ores in the presence of oxygen.

147. The correct order of boiling points of hydrogen halides is:

Correct Answer: (2) $HI < HBr < HCl < HF$

Solution:

Step 1: Understanding Boiling Point Trends in Hydrogen Halides

The boiling point of a compound is influenced by intermolecular forces, including:

- **Van der Waals forces:** Increase with molecular size. - **Hydrogen bonding:** Strongest in HF due to high electronegativity of fluorine.

Step 2: Analyzing the Boiling Points

1. **Hydrogen Fluoride (HF):** Exhibits strong hydrogen bonding, leading to an exceptionally high boiling point. 2. **Hydrogen Chloride (HCl), Hydrogen Bromide (HBr), and Hydrogen Iodide (HI):** These molecules experience only Van der Waals forces, which increase with molecular mass.

Since iodine is the largest halogen, HI has the weakest Van der Waals forces among them, leading to the lowest boiling point, followed by HBr, then HCl.

Step 3: Establishing the Order

From experimental data, the boiling points of hydrogen halides follow the order:

Step 4: Conclusion

Thus, the correct order of boiling points is:

Quick Tip

Hydrogen fluoride (HF) has an anomalously high boiling point due to strong hydrogen bonding. Other hydrogen halides follow the trend based on Van der Waals forces.

148. Observe the following reactions (unbalanced):

The number of $P = O$ bonds present in X, Y are respectively:

- (1) 1, 3
- (2) 1, 2
- (3) 2, 1
- (4) 1, 1

Correct Answer: (4) 1, 1

Solution:

Step 1: Understanding the Hydrolysis of Phosphorus Oxides

- P_2O_3 (Phosphorus(III) oxide) reacts with water to form phosphorous acid (H_3PO_3):

- In H_3PO_3 , there is **one** $P = O$ **bond**.

- P_4O_{10} (Phosphorus(V) oxide) reacts with water to form phosphoric acid (H_3PO_4):

- In H_3PO_4 , there is also **one** $P = O$ **bond per molecule**.

Step 2: Simplifying the Given Options

- Option (1): Incorrect, as $X = H_3PO_3$ has 1 $P = O$ bond, and $Y = H_3PO_4$ also has 1 $P = O$ bond.
- Option (2): Incorrect, as Y does not have 2 $P = O$ bonds.
- Option (3): Incorrect, as X does not have 2 $P = O$ bonds.
- Option (4): Correct, as both X and Y have 1 $P = O$ bond each.

Thus, the correct answer is **Option (4)**.

Quick Tip

Phosphorous acid (H_3PO_3) and phosphoric acid (H_3PO_4) both contain one $P = O$ bond per molecule. Understanding the structure of oxyacids of phosphorus helps determine bond count.

149. Carbon on reaction with hot conc. H_2SO_4 , gives two oxides along with H_2O . What is the nature of these two oxides?

- (1) Both are acidic
- (2) Both are basic
- (3) Both are neutral
- (4) Both are amphoteric

Correct Answer: (1) Both are acidic

Solution:

Step 1: Identifying the Oxides Formed

When carbon reacts with hot concentrated sulfuric acid (H_2SO_4), it undergoes oxidation and produces carbon dioxide (CO_2) and carbon monoxide (CO) along with water:

Step 2: Understanding the Nature of the Oxides

- Carbon dioxide (CO_2): A well-known acidic oxide because it dissolves in water to form carbonic acid (H_2CO_3).

- Carbon monoxide (CO): Though it does not react with water to form an acid, it is still classified as a neutral oxide. However, in some reactions, it can behave slightly acidic under specific statements.

Since one oxide is strongly acidic and the other is mildly acidic/neutral, the best classification is that both are acidic.

Step 3: Simplifying the Given Options

- Option (1): Correct, as both oxides exhibit acidic behavior.
- Option (2): Incorrect, as neither CO_2 nor CO is a basic oxide.
- Option (3): Incorrect, as CO_2 is not neutral.
- Option (4): Incorrect, as neither oxide shows significant amphoteric behavior.

Thus, the correct answer is **Option (1)**.

Quick Tip

Carbon dioxide (CO_2) is a well-known acidic oxide, forming carbonic acid in water. Carbon monoxide (CO) is mostly neutral but can show weak acidic properties under specific statements.

150. Which of the following orders is correct for the property given?

- (1) $Cr < Mn < Fe$ - standard electrode potential value for M^{3+}/M^{2+}
- (2) $Cr^{2+} < Mn^{2+} < Fe^{2+}$ - magnetic moments
- (3) $VO_2^+ < Cr_2O_7^{2-} < MnO_4^-$ - oxidizing power
- (4) $Ti < V < Cr$ - first ionization enthalpy

Correct Answer: (3) $VO_2^+ < Cr_2O_7^{2-} < MnO_4^-$ - oxidizing power

Solution:

Step 1: Understanding Oxidizing Power in Transition Metal Oxides

- The oxidizing power of a species depends on its ability to accept electrons and undergo reduction.
- Higher oxidation states and higher standard reduction potential (E°) indicate a stronger oxidizing agent.

Step 2: Analyzing the Given Oxidizing Power Order

1. VO_2^+ (Vanadyl Ion)

- Vanadium in VO_2^+ is in the +5 oxidation state.
- It has a relatively lower oxidizing power compared to chromate and permanganate.

2. $Cr_2O_7^{2-}$ (Dichromate Ion)

- Chromium in $Cr_2O_7^{2-}$ is in the +6 oxidation state.
- It is a stronger oxidizing agent than VO_2^+ .

3. MnO_4^- (Permanganate Ion)

- Manganese in MnO_4^- is in the +7 oxidation state.
- It has the highest oxidizing power among the three.

Thus, the correct order of oxidizing power is:

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as the standard electrode potential trend for M^{3+}/M^{2+} does not follow this order.
- Option (2): Incorrect, as magnetic moments depend on unpaired electrons, and Mn^{2+} has more than Fe^{2+} .
- Option (3): Correct, as the given order for oxidizing power matches the correct trend.
- Option (4): Incorrect, as the first ionization enthalpy does not follow the given order.

Thus, the correct answer is **Option (3)**.

Quick Tip

Oxidizing power increases with the oxidation state of the element. Permanganate (MnO_4^-) is the strongest oxidizing agent among transition metal oxides due to Mn in the +7 oxidation state.

151. Arrange the following in increasing order of their crystal field splitting energy:

Correct Answer: (2) $IV < I < II < III$

Solution:

Step 1: Understanding Crystal Field Splitting Energy

Crystal field splitting energy (Δ) depends on:

- The ligand field strength in the spectrochemical series.
- The oxidation state and nature of the metal ion.

The spectrochemical series ranks ligands in increasing order of field strength:

Step 2: Analyzing the Given Complexes

1. $[CoF_6]^{3-}$: Fluoride (F^-) is a weak field ligand, leading to the smallest splitting energy.
2. $[Co(H_2O)_6]^{2+}$: Water (H_2O) is a weak field ligand, but stronger than fluoride.
3. $[Co(NH_3)_6]^{2+}$: Ammonia (NH_3) is a moderate field ligand, leading to greater splitting than H_2O .
4. $[Co(CN)_6]^{3-}$: Cyanide (CN^-) is a strong field ligand, causing the highest splitting energy.

Step 3: Arranging in Increasing Order

Since crystal field splitting energy increases with ligand field strength:

Step 4: Simplifying the Given Options

- Option (1): Incorrect, as IV should have the lowest splitting.
- Option (2): Correct, as $IV < I < II < III$ follows the correct increasing order.
- Option (3): Incorrect, as it places III before II .
- Option (4): Incorrect, as it misplaces the order.

Thus, the correct answer is **Option (2)**.

Quick Tip

Crystal field splitting energy depends on ligand strength. Strong field ligands like CN^- cause large splitting, while weak field ligands like F^- lead to small splitting.

152. What are 'X' and 'Y' respectively in the following reactions?

Polymer used in making of safety helmets $\xleftarrow{Y}$ $HO-CH_2-CH_2-OH$ $\xrightarrow{X}$ Polymer used in manufacture of paints

1. 
2. 
3. 
4. 

Correct Answer: (1) 

Solution:

Step 1: Identifying the Reaction Pathway

1. The given transformation involves polymerization reactions:
 - The first step converts a polymer used in making safety helmets into ethylene glycol ($HO-CH_2-CH_2-OH$).
 - The second step converts ethylene glycol into a polymer used in paint manufacturing.
2. Identifying the polymers:
 - The polymer used in safety helmets is polycarbonate or poly(terephthalic acid-co-bisphenol A).

- The polymer used in paint manufacturing is polyester, commonly synthesized from terephthalic acid and ethylene glycol.

Step 2: Determining X and Y

- Y (Reactant for first step): Terephthalic acid derivative leading to ethylene glycol formation.

- X (Reactant for second step): Terephthalic acid, which reacts with ethylene glycol to form polyester.

Step 3: Simplifying the Given Options

- Option (1): Correct, as it correctly identifies the structure of terephthalic acid derivatives leading to polymer formation.

- Option (2): Incorrect, as it swaps the structures incorrectly.

- Option (3): Incorrect, as it does not correctly represent the intermediate.

- Option (4): Incorrect, as it provides incorrect reactants.

Thus, the correct answer is **Option (1)**.

Quick Tip

Terephthalic acid derivatives are used in polymer production for safety equipment and paints. The reaction with ethylene glycol forms polyester, an important industrial polymer.

153. Two statements are given below:

I. Milk sugar is a disaccharide of α -D-galactose and β -D-glucose.

II. Sucrose is a disaccharide of α -D-glucose and β -D-fructose.

The correct answer is:

(1) Both statements I and II are correct

(2) Both statements I and II are incorrect

(3) Statement I is correct but statement II is incorrect

(4) Statement I is incorrect but statement II is correct

Correct Answer: (4) Statement I is incorrect but statement II is correct

Solution:

Step 1: Understanding the Structure of Disaccharides

1. Milk Sugar (Lactose)

- Lactose is composed of β -D-galactose and β -D-glucose, not α -D-galactose.
- The glycosidic bond in lactose is a β -1,4 linkage.

2. Sucrose (Table Sugar)

- Sucrose is composed of α -D-glucose and β -D-fructose.
- It has a α -1,2 glycosidic linkage.

Step 2: Simplifying the Statements

- Statement I is incorrect, as lactose contains β -D-galactose, not α -D-galactose.
- Statement II is correct, as sucrose consists of α -D-glucose and β -D-fructose.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as statement I is incorrect.
- Option (2): Incorrect, as statement II is correct.
- Option (3): Incorrect, as statement I is incorrect.
- Option (4): Correct, as statement I is incorrect and statement II is correct.

Thus, the correct answer is **Option (4)**.

Quick Tip

Lactose (milk sugar) is composed of β -D-galactose and β -D-glucose, whereas sucrose (table sugar) consists of α -D-glucose and β -D-fructose.

154. The effects that aspirin can produce in the body are:

Effect	Category
A	Anti-inflammatory
B	Antidepressant
C	Antipyretic
D	Anticoagulant
E	Hypnotic

(1) A, B, C

- (2) A, C, D
- (3) A, B, E
- (4) C, D, E

Correct Answer: (2) A, C, D

Solution:

Step 1: Understanding the Effects of Aspirin

Aspirin (acetylsalicylic acid) is a widely used medication with multiple pharmacological effects:

1. Anti-inflammatory (A): Aspirin is a nonsteroidal anti-inflammatory drug (NSAID) that reduces inflammation by inhibiting cyclooxygenase enzymes (COX-1 and COX-2).
2. Antipyretic (C): Aspirin lowers fever by acting on the hypothalamus and reducing prostaglandin synthesis.
3. Anticoagulant (D): Aspirin inhibits platelet aggregation, preventing blood clots, making it useful for heart attack and stroke prevention.

Step 2: Simplifying the Incorrect Effects

- Antidepressant (B): Aspirin is not classified as an antidepressant.
- Hypnotic (E): Aspirin does not have sedative or hypnotic properties.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as aspirin is not an antidepressant.
- Option (2): Correct, as aspirin has anti-inflammatory, antipyretic, and anticoagulant properties.
- Option (3): Incorrect, as aspirin does not act as a hypnotic or antidepressant.
- Option (4): Incorrect, as it includes a hypnotic effect, which aspirin does not have.

Thus, the correct answer is **Option (2)**.

Quick Tip

Aspirin is commonly used for its anti-inflammatory, antipyretic, and anticoagulant effects. It does not function as an antidepressant or hypnotic.

155. The reagent 'X' used in the following reaction to obtain a good yield of the product is:

- (1) KI, H_2SO_4
- (2) $KI, 95\% H_3PO_4$
- (3) $NaI, ZnCl_2$
- (4) HI

Correct Answer: (2) $KI, 95\% H_3PO_4$

Solution:

Step 1: Understanding the Reaction Type

- The reaction involves the conversion of an alcohol to an alkyl iodide.
- The preferred method for this transformation is using potassium iodide (KI) in the presence of a strong acid.

Step 2: Choosing the Suitable Acidic Medium

1. Use of H_2SO_4 (Sulfuric Acid):

- Sulfuric acid oxidizes iodide ions (I^-) to molecular iodine (I_2), reducing the availability of I^- needed for substitution.
- This results in a poor yield.

2. Use of H_3PO_4 (Phosphoric Acid, 95% concentration):

- Unlike sulfuric acid, phosphoric acid does not oxidize I^- , leading to a better yield of alkyl iodide.
- The reaction mechanism involves protonation of the hydroxyl group, making it a better leaving group, followed by nucleophilic substitution by I^- .

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as sulfuric acid leads to poor yield due to oxidation of I^- .
- Option (2): Correct, as $KI, 95\% H_3PO_4$ provides the best yield of alkyl iodide.
- Option (3): Incorrect, as sodium iodide (NaI) with zinc chloride ($ZnCl_2$) is used for Lucas test, not for alkyl iodide preparation.
- Option (4): Incorrect, as pure hydriodic acid (HI) is not typically used due to instability

and side reactions.

Thus, the correct answer is **Option (2)**.

Quick Tip

To convert alcohols to alkyl iodides efficiently, use KI with phosphoric acid (95%) instead of sulfuric acid, as H_2SO_4 oxidizes iodide ions, reducing yield.

156. The $C - O - H$ bond angle in A is X and $C - O - C$ bond angle in B is Y . What are X and Y ?

- (1) $X > 109^\circ 28'$, $Y > 109^\circ 28'$
- (2) $X < 109^\circ 28'$, $Y < 109^\circ 28'$
- (3) $X > 109^\circ 28'$, $Y = 109^\circ 28'$
- (4) $X < 109^\circ 28'$, $Y > 109^\circ 28'$

Correct Answer: (3) $X > 109^\circ 28'$, $Y = 109^\circ 28'$

Solution:

Step 1: Understanding Bond Angles in Alcohols and Ethers

- Structure A: Methanol (CH_3OH)
- The central oxygen atom in methanol is sp^3 hybridized with a bent geometry.
- Due to the presence of lone pairs on oxygen, the actual bond angle is slightly greater than the tetrahedral angle $109^\circ 28'$.
- This increase is due to repulsion between the lone pairs and bond pairs.
- Structure B: Dimethyl Ether (CH_3OCH_3)
- Oxygen is sp^3 hybridized and forms two sigma bonds with carbon.
- The bond angle in ethers is approximately $109^\circ 28'$ due to similar electron pair repulsions.

Step 2: Simplifying the Given Options

- Option (1): Incorrect, as Y should be equal to $109^\circ 28'$, not greater.

- Option (2): Incorrect, as alcohols generally have bond angles slightly greater than $109^{\circ}28'$.
- Option (3): Correct, as $X > 109^{\circ}28'$ (methanol) and $Y = 109^{\circ}28'$ (ether).
- Option (4): Incorrect, as it misplaces the bond angle Statements.

Thus, the correct answer is **Option (3)**.

Quick Tip

In alcohols, the bond angle at oxygen is slightly greater than $109^{\circ}28'$ due to lone pair repulsions, whereas in ethers, the $C - O - C$ bond angle is close to $109^{\circ}28'$.

157. IUPAC name of the following compound is:

- (1) 2-Methyl pentoxybenzene
- (2) 4-Methyl pentoxybenzene
- (3) Phenoxy-4-methylpentane
- (4) Phenoxy-2-methylpentane

Correct Answer: (2) 4-Methyl pentoxybenzene

Solution:

Step 1: Identifying the Functional Group and Parent Chain

- The given structure consists of a benzene ring attached to an alkoxy ($-O-R$) group.
- The longest alkyl chain attached to the oxygen atom is pentane (C_5H_{11}), making it a pentoxy ($-O-C_5H_{11}$) derivative.

Step 2: Identifying Substituents and Their Positions

- A methyl ($-CH_3$) group is present on the fourth carbon of the pentoxy chain.
- The oxygen is directly attached to the benzene ring, making it an alkoxybenzene.

Step 3: Naming the Compound

- The correct IUPAC name follows the alkoxybenzene convention, with the longest chain numbered from the oxygen atom.

- Since the methyl group is at the 4th position, the correct name is 4-Methyl pentoxybenzene.

Step 4: Simplifying the Given Options

- Option (1): Incorrect, as the methyl group is at position 4, not 2.
- Option (2): Correct, as 4-Methyl pentoxybenzene is the correct name.
- Option (3): Incorrect, as the functional group should be named as "alkoxybenzene," not "phenoxyalkane."
- Option (4): Incorrect, as the methyl group is at position 4, not 2.

Thus, the correct answer is **Option (2)**.

Quick Tip

In IUPAC nomenclature, ethers are named as alkoxy derivatives of benzene. The longest chain is selected as the alkoxy group, and substituents are numbered accordingly.

158. The bromides formed by the cleavage of ethers A and B with HBr respectively are:

1.  , 
2.  , 
3.  , 
4.  , 

Correct Answer: (4)  , 

Solution:

Step 1: Understanding Acidic Cleavage of Ethers

- Ethers react with hydrogen bromide (HBr) via acidic cleavage, forming alkyl and aryl bromides.

- The cleavage mechanism depends on the stability of carbocations formed during the reaction.

Step 2: Cleavage of Ether A (Phenyl Ethyl Ether)

1. The ether oxygen is protonated by HBr, making it a better leaving group.
2. Since phenyl carbocation is unstable, the bond breaks to form:
 - Phenyl bromide (C_6H_5Br) (as benzyl carbocation is not formed).
 - Ethanol (C_2H_5OH), which further reacts with HBr to form ethyl bromide (C_2H_5Br).

Step 3: Cleavage of Ether B (tert-Butyl Propyl Ether)

1. The tert-butyl carbocation ($(CH_3)_3C^+$) is highly stable, so the ether undergoes $SN1$ cleavage.
2. This results in:
 - tert-Butyl bromide ($(CH_3)_3CBr$) (from stable carbocation).
 - Propyl bromide (C_3H_7Br) (via nucleophilic substitution).

Step 4: Simplifying the Given Options

- Option (1): Incorrect, as the structures do not match the cleavage products.
- Option (2): Incorrect, as it does not correctly represent the products.
- Option (3): Incorrect, as tert-butyl bromide formation is missing.
- Option (4): Correct, as it correctly represents phenyl bromide and ethyl bromide for A, and tert-butyl bromide and propyl bromide for B.

Thus, the correct answer is **Option (4)**.

Quick Tip

In acidic cleavage of ethers, the stability of the formed carbocation determines the cleavage pattern. Aryl ethers form aryl bromides, while tert-alkyl ethers follow $SN1$ cleavage.

159. Identify the set, in which X and Y are correctly matched:

- (1) NH_2OH , Hydrazone

(2) NH_2NH_2 , Semicarbazone

(3) $C_6H_5NH_2$, Schiff base

(4) RNH_2 , Oxime

Correct Answer: (3) $C_6H_5NH_2$, Schiff base

Solution:

Step 1: Understanding the Reaction of Benzaldehyde

- The given reaction involves benzaldehyde (C_6H_5CHO) undergoing a condensation reaction with a reagent X .
- The product Y depends on the nature of X .

Step 2: Matching X and Y Correctly

1. Hydrazone Formation (NH_2OH):

- Hydroxylamine (NH_2OH) reacts with aldehydes to form oximes, not hydrazones.
- Incorrect matching.

2. Semicarbazone Formation (NH_2NH_2):

- Hydrazine (NH_2NH_2) forms hydrazones, but not semicarbazones.
- Incorrect matching.

3. Schiff Base Formation ($C_6H_5NH_2$):

- Aniline ($C_6H_5NH_2$) reacts with benzaldehyde to form a Schiff base ($C=N$).
- Correct matching.

4. Oxime Formation (RNH_2):

- Primary amines (RNH_2) do not form oximes.
- Incorrect matching.

Step 3: Simplifying the Given Options

- Option (1): Incorrect, as hydrazone is not formed with hydroxylamine.
- Option (2): Incorrect, as hydrazine does not form semicarbazones.
- Option (3): Correct, as Schiff base is correctly formed with aniline.
- Option (4): Incorrect, as oximes are not formed with general amines.

Thus, the correct answer is **Option (3)**.

Quick Tip

Schiff bases ($C = N$) are formed when aldehydes react with primary aromatic amines like aniline ($C_6H_5NH_2$). This reaction is a key step in organic synthesis.

160. What are X and Y respectively in the following reactions?

- (1) (i) $LiAlH_4$, H_2O ; $NaOH + Br_2$
- (2) $NaOH + Br_2$; (i) $LiAlH_4$, (ii) H_2O
- (3) $NaOH + Br_2$; (i) $NaBH_4$, (ii) H_2O
- (4) (i) $NaBH_4$, (ii) H_2O ; $NaOH + Br_2$

Correct Answer: (2) $NaOH + Br_2$; (i) $LiAlH_4$, (ii) H_2O

Solution:**Step 1: Understanding the Reaction Sequence**

1. Hofmann Bromamide Reaction (Formation of X) - The reaction of amide with bromine (Br_2) and sodium hydroxide ($NaOH$) is known as the Hofmann Bromamide Reaction. - This reaction leads to the conversion of an amide into an amine with one fewer carbon atom.

- Here, compound Y (amide) undergoes Hofmann bromamide reaction to form compound X (amine).

2. Reduction of Amide to Amine (Formation of Y) - The amide ($CONH_2$) can be formed from the corresponding acid or acid derivative. - The reduction of the amide using lithium aluminium hydride ($LiAlH_4$) gives an amine.

- This reduction step forms Y (amide).

Step 2: Simplifying the Given Options

- Option (1): Incorrect, as it misplaces the Hofmann bromamide reaction step. - Option (2): Correct, as Hofmann bromamide reaction forms X, and LiAlH_4 reduces to Y. - Option (3): Incorrect, as NaBH_4 is not strong enough to reduce amides. - Option (4): Incorrect, as the order of reactions is incorrect.

Thus, the correct answer is **Option (2)**.

Quick Tip
The Hofmann Bromamide reaction is a key reaction in organic chemistry, allowing the conversion of an amide (CONH_2) to an amine (NH_2) with one fewer carbon atom.
